ABSTRACT

The purpose of the present study was to investigate the potential cardioprotective effects of an original approach based on the properties of the X chromosome-linked Inhibitor of Apoptosis (XIAP), the most effective endogenous inhibitor of apoptosis. For this purpose, the C-terminal part of XIAP (BIR3 and RING domains) was fused to the protein transduction domain (PTD) of the HIV1 transactivator of transcription, which confers to fused protein the ability to cross cell membranes. This protein, so-called PTD-BIR3/RING, was administered intravenously in C57BL/6J mice subjected to 30 min coronary artery occlusion and 24 h of reperfusion. Administration of PTD-BIR3/RING at 5 min before and 30 min after the onset of reperfusion reduced infarct size *vs* control ($23\pm 2\%$ *vs* $41\pm 4\%$ and $27\pm 4\%$ *vs* $41\pm 3\%$, respectively, $p < 0.05$). Similar reduction in infarct size was observed when PTD-BIR3/RING was administered prior to ischemia ($28\pm 1\%$ *vs* $44\pm 3\%$). In addition to inhibition of caspase-3 and -9 activities, PTD-BIR3/RING induced an inhibition of caspase-8 and several other actors of the apoptotic pathways. In conclusion, this study demonstrates that the administration of PTD-BIR3/RING reduces myocardial infarct size even when injected during reperfusion through interruption of caspase activation by pharmacologically mimicking endogenous XIAP.

Key words: Cardioprotection, infarction, XIAP, reperfusion, caspase activity.

INTRODUCTION

Although the current therapeutic strategy during acute myocardial infarction is to re-establish coronary blood flow by angioplasty, thrombolysis or cardiac surgery, the associated morbidity and mortality remain important and therefore require additional cardioprotection. For many years, different approaches such as early and delayed preconditioning (1, 2), pharmacological cardioprotection (3-6) or more recently postconditioning, *i.e.*, brief interruptions of reperfusion with short episodes of myocardial ischemia (7) have been extensively investigated in this regard. Interestingly, clinical studies have demonstrated the benefit of ischemic postconditioning in patients with acute myocardial infarction (8-10). However, the clinical translation of almost all these strategies is limited by the schedule of treatment as they must be applied either before the onset of ischemia or within the very first minutes of reperfusion (11-13) and also by the fact that postconditioning is restricted to patients who are undergoing percutaneous coronary intervention. Therefore, the development of other cardioprotective strategies still remains a major challenge.

Cell death after ischemia-reperfusion occurs at least by necrosis and apoptosis. Apoptosis is a programmed cell death controlled by the death receptor, the mitochondrial pathways through caspase activation and also endogenous regulators of apoptotic cell death. In this setting, XIAP (X chromosome-linked Inhibitor of Apoptosis) is a major inhibitor of apoptosis in cardiomyocyte (14) and ischemia or hypoxia are known to reduce XIAP expression (15, 16). XIAP possesses three baculovirus IAP repeat (BIR1, BIR2 and BIR3) domains and a RING (really interesting new gene) domain. The BIR3 domain interacts with caspase-9 (17) while the RING domain possesses a E3 ligase activity and is implicated in proteasome-related degradation of a number of substrates that include caspase-3 (18). Among the endogenous inhibitors of apoptosis such as IAP1, IAP2, ILP2, MLIAP, NIAP, XIAP is the best

characterized of mammalian IAPs and it is also the most potent and versatile of these regulators of cell death (19, 20). XIAP mRNA has been observed in all adult and fetal tissues examined except peripheral blood leukocytes, indicating that it is an ubiquitous expressed member of the IAP family (21).

Accordingly, the aim of the present study was to examine whether the C-terminal part of XIAP (BIR3 and RING domains) fused to the protein transduction domain (PTD) of the TAT-fusion system (HIV1 transactivator of transcription), *i.e.*, PTD-BIR3/RING, could protect the myocardium against infarction. Fusion of BIR3/RING domains with TAT confers to this aminoacidic sequence the ability to cross cell membranes with a great efficacy (22), thereby decreasing the amount of protein needed for biological efficacy. We hypothesized that a beneficial effect could be observed when PTD-BIR3/RING is administered before but also during reperfusion, by pharmacologically mimicking the effects of XIAP. In addition, we also investigated several proteins that play important roles in the apoptotic transduction signaling along with caspase activities.

METHODS

The experiments were performed in accordance with the official regulations of the French Ministry of Agriculture. The authors have been granted a license from the institutional office “Préfecture du Val de Marne” (France) to conduct animal research (n° A 94-028-245).

Generation, production and purification of PTD-BIR3/RING

A construct encoding the BIR3/RING domains of XIAP was amplified from the cDNA of the entire reading frame of rat XIAP and purified fragments were cloned into the *XhoI/EcoRI* sites of the pTAT-HA vector (23). The final cDNA encoded a protein comprising a 6-histidine residues tag, the PTD sequence of TAT, a hemagglutinin (HA) tag and BIR3/RING sequences. Plasmids, *i.e.*, the PTD-BIR3/RING and PTD-HA alone were expressed in the *E. coli* strain BL21(DE3) pLysS (Stratagene, La Jolla, CA, USA) as previously described (23). Protein production was induced by addition of 500 μ M isopropyl 1-thio- β -D-galactoside. Proteins were extracted in 8M urea HEPES buffer and were purified using a Ni-NTA superflow agarose column (Qiagen, Hilden, Germany). Salt was removed using dialysis (Pierce Biotechnology Inc, Rockford, IL, USA) and proteins were collected in a solution containing phosphate buffered saline. The molecular weight of purified proteins was verified by Coomassie blue staining of electrophoresis gels.

Animal model of myocardial infarction

Male C57BL6/J mice (6-8 weeks) were anesthetized by intraperitoneal injection of pentobarbital sodium (50 mg/kg), intubated and ventilated mechanically. The body temperature was measured using a rectal probe and was maintained at 37°C with a blanket connected to an homeothermic regulator (Homeo-blanket system 50-7221F, Harvard Apparatus, Les Ulis, France). A small catheter was inserted into a jugular vein for

administration of the treatment and a thoracotomy was performed. A coronary artery occlusion and reperfusion was achieved with an 8-0 Prolene thread placed around the left coronary artery as previously described (24). Myocardial ischemia was confirmed by ST segment deviation of the electrocardiogram and the occurrence of regional cyanosis. Reperfusion was confirmed by visualisation of hyperemic response and the chest was closed in layers.

Experimental protocol

The experimental protocols are shown in figure 1. To determine the effects of PTD-BIR3/RING on myocardial infarct size, mice underwent 30 min of coronary artery occlusion followed by 24 h of reperfusion. In these experiments, PTD-BIR3/RING (0.8 μ g/g) was injected intravenously either 5 min before ischemia as well as 5 min before and 30 min after the onset of reperfusion. The dose of 0.8 μ g/g was chosen on the basis of preliminary experiments investigating the infarct-limiting effects of increasing doses of PTD-BIR3/RING. The control groups were treated with vehicle (phosphate buffer saline) 5 min before ischemia, 5 min before and 30 min after the onset of reperfusion. Although it would have been more appropriate to use PTD-HA in the control mice, it is unlikely that the use of phosphate buffer saline represents an experimental bias as we verified that administration of PTD-HA (1 mg/ml and 0.8 μ g/g) alone at 30 min of reperfusion did not elicit proper effects on myocardial infarct size (40 \pm 4%, n=6 vs 41 \pm 3%, n= 9 for PTD-HA and phosphate buffer saline-treated mice, respectively).

Assessment of infarct size

At the end of the 24 h reperfusion period, the coronary artery was reoccluded at the previous site of occlusion. The area at risk was identified by negative Evan's blue dye staining and the infarct area was identified by triphenyltetrazolium chloride (TTC) negative

staining. The area at risk was expressed as a percentage of the left ventricle weight. The infarcted area was expressed as percentages of the area at risk.

Histology

Briefly, formalin-fixed slices of infarcted hearts were embedded in paraffin for histological analysis. Five micrometers-thick sections were cut from each paraffin block and stained with H&E (Hematoxylin&Eosin).

Caspase activity assay

In these experiments, PTD-BIR3/RING (0.8 $\mu\text{g/g}$) was administered at 30 min of reperfusion and proteins were extracted from left ventricles after 1 h, 3 h and 24 h of reperfusion and assayed for caspase activity (figure 1). Extraction was also performed in 3 additional mice that did not undergo ischemia-reperfusion. Tissues were homogenized in cold buffer (25mM HEPES pH 7.5, 5mM MgCl_2 , 2mM EDTA, 0.1% Triton X100, 2mM dithiothreitol, 1mM PMSF, 5 $\mu\text{l/ml}$ protease cocktail inhibitor P8849, Sigma-Aldrich, St Louis, MO, USA). Homogenates were centrifuged and supernatants were collected. Proteins (50 μg) were incubated in caspase assay buffer (50mM HEPES pH 7.4, 100mM NaCl, 1mM EDTA, 10mM dithiothreitol). Enzymatic reaction was started by addition of 0.2mM of the fluorogenic substrates ac-DEVD-AFC, ac-IETD-AFC, ac-LEHD-AFC (Biomol Research Laboratories, Hambourg, Germany) to caspase-3, caspase-8 and caspase-9, respectively. Fluorescent arbitrary units were converted into $\mu\text{moles of AFC/h/mg protein}$ using a standard curve of free AFC (Sigma-Aldrich, St Louis, MO, USA).

Western blot analysis

In these experiments, PTD-BIR3/RING (0.8 $\mu\text{g/g}$) was administered at 30 min of reperfusion and proteins were extracted from left ventricles after 1 h reperfusion (figure 1). Myocardial

samples were placed in medium containing 220mM Mannitol, 70mM Sucrose, 10mM HEPES, 1mM EGTA, 1mM PMSF, 5mM NaF, 1mM Na₃VO₄, 1mM Na₂ Glycerol 2-phosphate, 5µl/ml protease inhibitor cocktail (Sigma-Aldrich, St Louis, MO, USA), pH 7.4 at 4 °C. The tissue was minced with scissors and homogenized on ice using a Teflon Potter homogenizer. The homogenate was centrifuged at 1000g for 5 min to remove cellular debris and nuclei. The supernatant was centrifuged for 10 min at 10 000g to obtain the mitochondrial pellet. The latter was washed with the same medium and centrifuged at 10 000g for 10 min. The resulting mitochondrial pellet was resuspended with medium, frozen and thawed several times, and finally sonicated to extract the mitochondrial content. The 10 000g supernatant was centrifuged at 17 600g for 30 min. The resulting supernatant was the cytosolic fraction. In order to check for the absence of mitochondrial contamination of the cytosolic fraction, we verified the absence of citrate synthase activity in the cytosolic samples.

Proteins were separated on 10-15% SDS-polyacrylamide gels using 40-80µg proteins per lane and transferred onto PVDF membranes (Millipore Corporate, Billerica, MA, USA). After blocking with 5% dry milk in Tris-buffered saline containing 0.1% Tween-20 (TBS-T), membranes were incubated for 1 h at room temperature with the following antibodies: rabbit polyclonal anti-phospho-Bad 1:200 (at Ser¹³⁶), rabbit polyclonal anti-Bad 1:250, rabbit polyclonal anti-COX IV 1:3000 (an enzyme localized in the inner mitochondrial membrane used as a mitochondrial loading control; Cell Signaling Technology Inc, Danvers, MA, USA), rabbit polyclonal anti-Bax 1:500, goat polyclonal anti-Smac/DIABLO 1:200, goat polyclonal anti-actin 1:3000 (Santa Cruz Biotechnology Inc, Santa Cruz, CA, USA), goat polyclonal t-Bid and total Bid 1:1000 (R&D Systems Inc, Minneapolis, MN, USA). Membranes were then washed three times with TBS-T for 10 min and subsequently incubated for 1 h with the appropriate secondary antibody conjugated to horseradish peroxidase (Santa Cruz Biotechnology Inc, Santa Cruz, CA, USA). Bands were visualized with chemiluminescence

(Pierce ECL Western Blotting Substrate, Pierce Biotechnology Inc, Rockford, IL, USA) and analysed with the Image J software (NIH, Bethesda, MA, USA).

Statistical analysis

All values are expressed as mean \pm SEM for the number of samples indicated in the legends of figures. Comparisons between groups were assessed using ANOVA followed if necessary by Student's *t*-test. Statistical significance was defined as a value of $p < 0.05$.

RESULTS

Effect of PTD-BIR3/RING on myocardial infarct size

As shown in table 1, animal body weights and sizes of area at risk were similar among groups. As illustrated in figure 2, PTD-BIR3/RING significantly reduced infarct size as compared to Control when administered 5 min before and 30 min after the onset of reperfusion ($23\pm 2\%$ vs $41\pm 4\%$ and $27\pm 4\%$ vs $41\pm 3\%$, respectively). Similar reduction in infarct size was observed when PTD-BIR3/RING was administered prior to ischemia ($28\pm 1\%$ vs $44\pm 3\%$).

Histology

In contrast with the major difference in infarct size between the two groups, histological analysis only revealed moderate different patterns of lesions within the infarct as shown in figure 3. In control mice, the main focus of infarction demonstrated a homogenous pattern of cell death whereas in PTD-BIR3/RING treated mice, it was less homogenous and made of patchy foci of cell death.

Caspase activities

In control mice, caspase-3, caspase-8 and caspase-9 activities were increased at 3 h of reperfusion as illustrated in figure 4. When PTD-BIR3/RING was administered at 30 min of reperfusion, these increases were significantly blunted by PTD-BIR3/RING. After 24 h of reperfusion, all caspase activities were similar in the PTD-BIR-3/RING and control mice and these values were similar to those observed in mice that did not suffer ischemia-reperfusion (61 ± 14 , 69 ± 7 and 7 ± 1 $\mu\text{M AFC/h/mg protein}$ for caspase-3, -8 and -9, respectively).

Western blot analysis

As illustrated in figure 5, the phosphorylated Bad/Bad ratio was significantly increased in PTD-BIR3/RING treated mice (+342 %) as compared to Control. Concomitantly with inhibition of caspase-8 activity, we observed that the ratio of truncated Bid to total Bid was significantly reduced by PTD-BIR3/RING (-41 %). In addition, as several pro-apoptotic proteins are known to translocate between the cytosol and the mitochondria, we analysed their subcellular location. Analysis of the cytosolic and mitochondrial fractions revealed that PTD-BIR3/RING significantly increased the Bax cytosolic to mitochondrial ratio as compared to Control. Finally, Smac/DIABLO cytosolic to mitochondrial ratios were similar between the two groups.

DISCUSSION

The present study demonstrates that the administration of BIR3/RING using the protein transduction domain (PTD) of the TAT-fusion system, *i.e.*, PTD-BIR3/RING up to 30 min during reperfusion significantly reduces myocardial infarct size in mice subjected to 30 min coronary artery occlusion. The novel finding is that the previously ischemic myocardium can be salvaged by pharmacologically mimicking the effects of XIAP during reperfusion. This is consistent with a previous report demonstrating that overexpression of the endogenous inhibitor IAP-2 significantly reduces myocardial infarct size and apoptosis (25). The beneficial effect observed in our study was achieved through inhibiting caspase-mediated cell death pathways. Besides inhibition of caspase-3 and -9, PTD-BIR3/RING also blunted the increase in caspase-8 activity. This was associated with the reduction of ischemia-induced truncation of Bid, a target of caspase-8, and inactivation of key players of the apoptotic mitochondrial pathway such as the Bcl-2 family members Bax and Bad. Interestingly, PTD-BIR3/RING administered prior to ischemia or reperfusion did not afford a higher degree of protection than when administered at reperfusion suggesting that the cardioprotective effect of PTD-BIR3/RING is mainly related due to the interruption of deleterious signaling pathways that are activated during reperfusion.

Among numerous proteins that are known to regulate caspase activity, XIAP is the most potent inhibitor of apoptosis (26). The PTD peptide of the HIV1-TAT can enter into the cells efficiently when added exogenously and allows cellular delivery of macromolecules. In the present study, PTD-BIR3/RING had kept its main biological activity as its administration abolished the increases in caspase-3 and caspase-9 activities during reperfusion. More importantly, it has been demonstrated, using purified recombinant proteins, that the BIR3 domain is the minimal region of XIAP needed for potent caspase-9 inhibition (17) and that the

RING domain of XIAP is essential for destruction of caspase-3 through the proteasome (18, 21). Caspase-9 is an initiator caspase that is in the first wave of activation when apoptosis is triggered. Caspase-3 is activated through the action of initiator caspases and its activation results in irreversible cell damage and death (27). Histological analysis revealed differential tissular aspects as, in contrast to control mice, the main focus of infarct in the PTD-BIR3/RING treated mice was less homogeneous suggesting patchy areas of salvaged tissues. It should also be considered that Smac/DIABLO is released by the mitochondria into the cytosol where it binds to IAPs, displacing caspases and thus enhancing the apoptotic signal (28). In our experimental conditions, we observed that the cytosolic to mitochondrial ratio of Smac/DIABLO was unchanged in PTD-BIR3/RING treated mice. We cannot exclude that part of PTD-BIR3/RING was inhibited by Smac/DIABLO. Nevertheless, the effects observed in PTD-BIR3/RING treated animals indicate that the amount of administered PTD-BIR3/RING override the endogenous inhibitory effect of Smac/DIABLO.

We also demonstrated for the first time that PTD-BIR3/RING inhibits caspase-8 activity. This result is of great importance as caspase-8 is at crossroads between the extrinsic and intrinsic apoptosis pathways (27) and plays multiple roles in apoptosis (29). Besides being an initiator caspase of the death-receptors pathway, caspase-8 exhibits a direct protease activity in the nucleus and plays an amplificatory role of the mitochondrial apoptotic pathway by cleavage and activation of the Bcl-2-related pro-apoptotic molecule Bid. Truncated Bid activates another member of the Bcl-2 family, Bax, which translocates into the outer mitochondrial membrane and participates to the pore formation. The resulting release of apoptogenic factors activates effector caspases. Consistent with its protective effect, PTD-BIR3/RING induced a significant decrease in truncated Bid and reduced the translocation of Bax from the cytosol to the mitochondria as demonstrated by the reduction in Bax cytosolic to

mitochondrial ratio. PTD-BIR3/TING was also responsible for an increase in the phosphorylation of Bad favouring its cytosolic sequestration.

Although we did not specifically investigate the mechanisms of caspase-8 inhibition by PTD-BIR3/RING, some hypotheses can be raised. CARPs (caspase-8 and -10 associated RING proteins) represent a family of anti-apoptotic proteins that specifically bind to and regulate DED (death effector domain) caspases such as caspase-8. Their RING domain possesses a high homology with the IAP family and exhibits a E3 ligase activity which may contribute to the ubiquitin-mediated proteolysis of DED caspases (30). It has also been demonstrated in epithelial cancer cell lines that activated caspase-3 cleaves and activates caspase-8 (31). One could therefore speculate that inhibition of caspase-8 activity by PTD-BIR3/RING may involve the E3 ubiquitin ligase activity of its RING domain or an indirect inhibition through caspase-3 inhibition. However, investigation of these issues was beyond the scope of this study.

It is also important to emphasize that the beneficial effects of PTD-BIR3/RING were still observed when administered up to 30 min after the onset of reperfusion. To date, the so-called postconditioning or the administration of pharmacological agents have to be started within the very first minutes of reperfusion to be efficient. Indeed, starting administration of the adenosine agonist agent AMP579 after 10 min of reperfusion or postconditioning after the first minutes of reperfusion is too late (11, 12). Such delayed cardioprotective effect of PTD-BIR3/RING is rather similar to that reported with other pharmacological strategies (32, 33). Finally, previous studies have also reported the beneficial effects of several caspase inhibitors but the administration of the blockers was started before the onset of reperfusion (34-37).

In conclusion, this study demonstrates that the administration of PTD-BIR3/RING reduces myocardial infarct size even when administered during reperfusion. PTD-BIR3/RING exerts

its cardioprotective effect through the interruption of caspase activation by pharmacologically mimicking endogenous XIAP.

ACKNOWLEDGEMENTS

This study was supported by grants from ACI 2003 “Plateforme d’exploration fonctionnelle thématifiée” [R03020JJ] and INSERM transfert [03202A10]. The authors wish to thank Valérie Martin for her technical help.

LEGEND OF FIGURES

Figure 1

Experimental protocols (CAO: coronary artery occlusion; CAR: coronary artery reperfusion) in mice receiving either vehicle (Control) or PTD-BIR3/RING (BIR, 0.8 $\mu\text{g/g}$). The arrows indicate the timing of PTD-BIR3/RING administration.

Figure 2

Individual and averaged values of infarct size expressed as percentage of the area at risk (AAR) measured at 24 h of coronary artery reperfusion (CAR) after 30 min coronary artery occlusion (CAO) in Control (C) and PTD-BIR3/RING-treated mice (BIR, 0.8 $\mu\text{g/g}$). *, $p < 0.05$ vs corresponding Control.

Figure 3

Histological analysis with H&E staining in control mice (panels A-C) and PTD-BIR3/RING treated mice (panels D-F).

A: At low magnification the main focus of infarction is quite homogeneous and made of dead cells. On the left of the figure, note the viable area of the myocardium (bar = 100 μm); B: Higher magnification clearly shows the homogeneous pattern of cell death within the main infarct focus (bar = 50 μm); C: At the periphery of the main focus, note the patchy pattern mode of individual or grouped cells (bar = 50 μm); D: At low magnification, the main focus of infarction is less homogeneous and made of patchy areas of cell death (bar = 100 μm). E: Higher magnification confirms the panel D (bar = 50 μm). F: At the periphery of the main infarct focus, note the patchy pattern of cell death (bar = 50 μm).

Figure 4

Caspase activities in Control (open bars) and PTD-BIR3/RING-treated mice (shaded bars) at 30 min of reperfusion. Measurements were performed at 1 h, 3 h and 24 h of coronary artery reperfusion (CAR). *, $p < 0.05$ vs corresponding Control.

Figure 5

Representative Western blots showing that PTD-BIR3/RING (BIR, shaded bars) administered at 30 min of reperfusion induced significant increase of phosphorylated Bad/Bad, Bax cytosolic to mitochondrial ratio as well as reduction in Bid truncation as compared to Control (C, open bars). Smac/DIABLO cytosolic to mitochondrial ratio was similar between PTD-BIR3/RING and Control. *, $p < 0.05$ vs corresponding Control.

Table 1. Body weights and areas at risk

Timing of administration	n	BW (g)	AAR (% LV)
<i>5 min before CAO</i>			
Control	5	25 ± 2	37 ± 3
PTD-BIR3/RING	4	24 ± 1	38 ± 4
<i>5 min before CAR</i>			
Control	6	26 ± 3	40 ± 3
PTD-BIR3/RING	6	23 ± 1	36 ± 3
<i>30 min CAR</i>			
Control	9	26 ± 3	39 ± 3
PTD-BIR3/RING	9	27 ± 3	45 ± 3

Values are mean ± s.e.m.

AAR: area at risk; BW: body weight; CAO: coronary artery occlusion

CAR: coronary artery reperfusion; LV: left ventricle.
