DNA methyltransferase 1 functions through C/ebpa to maintain hematopoietic stem and progenitor cells in zebrafish

Xiaohui Liu¹, Xiaoe Jia², Hao Yuan¹, Ke Ma², Yi Chen³, Yi Jin³, Min Deng⁴, Weijun Pan², Saijuan Chen¹, Zhu Chen¹, Hugues de The^{1,5}, Leonard I Zon⁶, Yi Zhou^{6*}, Jun Zhou^{1*} and Jun Zhu^{1,5*}

Abstract

Background: DNA methyltransferase 1 (Dnmt1) regulates expression of many critical genes through maintaining parental DNA methylation patterns on daughter DNA strands during mitosis. It is essential for embryonic development and diverse biological processes, including maintenance of hematopoietic stem and progenitor cells (HSPCs). However, the precise molecular mechanism of how Dnmt1 is involved in HSPC maintenance remains unexplored.

Methods: An N-ethyl-N-nitrosourea (ENU)-based genetic screening was performed to identify putative mutants with defects in definitive HSPCs during hematopoiesis in zebrafish. The expression of hematopoietic markers was analyzed via whole mount *in situ* hybridization assay (WISH). Positional cloning approach was carried out to identify the gene responsible for the defective definitive hematopoiesis in the mutants. Analyses of the mechanism were conducted by morpholino-mediated gene knockdown, mRNA injection rescue assays, anti-phosphorylated histone H3 (pH3) immunostaining and TUNEL assay, quantitative real-time PCR, and bisulfite sequencing analysis.

Results: A heritable mutant line with impaired HSPCs of definitive hematopoiesis was identified. Positional cloning demonstrated that a stop codon mutation was introduced in *dnmt1* which resulted in a predicted truncated Dnmt1 lacking the DNA methylation catalytic domain. Molecular analysis revealed that expression of CCAAT/enhancer-binding protein alpha (C/ebpa) was upregulated, which correlated with hypomethylation of CpG islands in the regulation regions of *cebpa* gene in Dnmt1 deficient HSPCs. Overexpression of a transcriptional repressive SUMO-C/ebpa fusion protein could rescue hematological defects in the *dnmt1* mutants. Finally, *dnmt1* and *cebpa* double null embryos exhibited no obvious abnormal hematopoiesis indicated that the HSPC defects triggered by *dnmt1* mutation were C/ebpa dependent.

Conclusions: Dnmt1 is required for HSPC maintenance via *cebpa* regulation during definitive hematopoiesis in zebrafish.

Background

In vertebrates, hematopoiesis takes place in two consecutive waves, primitive and definitive ones [1,2]. Primitive hematopoiesis, also known as embryonic hematopoiesis, predominantly produces erythroid and myeloid cells [3,4]; while definitive hematopoiesis, also called adult hematopoietic wave, generates hematopoietic stem cells (HSCs) that are capable of producing all lineages of blood [5]. The zebrafish (*Danio rerio*) is an excellent genetic system for the study of hematopoietic development [6,7], especially by characterization of thousands of mutants isolated from large-scale forward genetic screens [8,9]. In zebrafish, definitive HSCs arise from the ventral wall of the dorsal aorta (VDA), the zebrafish equivalent of the aorta/gonad/mesonephros (AGM) of mammals [10,11], then HSCs migrate through the caudal hematopoietic tissue (CHT) to the thymus and kidney marrow [12], where adult hematopoiesis occurs, similar to HSC migration through fetal liver and home to bone marrow in mammals.

The molecular regulation of hematopoiesis includes interactions of lineage-specific transcription factors and a series of epigenetic modifications, such as DNA methylation and covalent histone tail modifications [13]. DNA methylation is an important epigenetic regulation mechanism that regulates normal development through influencing gene transcription, genomic imprinting, and genome stability in mammalian cells [14-16]. In hematologic malignancies, dysregulation of DNA methylation may result in global shifts in gene expression, which frequently leads to increased self-renewal in malignant blood cells at the expense of normal differentiation [17].

Three active DNMTs, namely DNMT1 [18], DNMT3A, and DNMT3B [19,20], have been identified in mammals. DNMTs are highly evolutionarily conserved with a regulatory region attached to a catalytic domain [21]. DNMT1 is the most abundant DNA methyltransferase in mammalian cells and considered to be the key maintenance methyltransferase [22]. In mammals, DNMT1 null mutant embryonic stem cells are viable and contain a small percentage of methylated DNA and methyltransferase activity [23]. Mouse embryos homozygous for a deletion of *Dnmt1* die at 10 to 11 days gestation due to development defects [24]. Reduced Dnmt1 activity in xenopus [25] and zebrafish [26,27] has similar consequences. Dnmt1 also plays important roles in HSPCs. The deletion of *Dnmt1* has no influence on the mature cells in the hematopoietic system but causes decreased niche retention and self-renewal and differentiation defects of HSPCs [28]. In acute myeloid leukemia (AML), the expression of DNMTs is upregulated [29]. Conditional knockout of *Dnmt1* blocks development of leukemia, and haploinsufficiency of Dnmt1 is sufficient to delay progression of leukemogenesis and impair leukemia stem cell (LSC) self-renewal without altering normal hematopoiesis [30]. The precise mechanism of the

Dnmt1 regulation of HSC function requires further investigation.

In this study, a heritable zebrafish mutant line with hematopoietic defects identified through ENU-based forward genetic screening was found defective in *dnmt1* gene. Phenotype characterization of *dnmt1* mutant has uncovered severely impaired definitive hematopoiesis. Further molecular mechanistic studies revealed that *cebpa* was a Dnmt1 downstream target gene and activated as a result from hypomethylation of its regulation regions in *dnmt1* mutants, which suggested *cebpa* was a key downstream target of *dnmt1* gene in HSPCs. We further demonstrated that the elevated C/ebpa activity was required and accounted for, at least in part, the defective definitive hematopoiesis.

Results

Zebrafish mutant line ldd794 displays impaired definitive hematopoiesis

To search for novel genes involved in regulating definitive hematopoiesis, we established an ENU-based genetic screening strategy to identify putative mutants with defects in definitive HSPCs in zebrafish. Whole-mount mRNA *in situ* hybridization (WISH) analysis of *cmyb* [31], a marker of HSPCs, was used to screen for mutants. In the mutant line ldd794, *cmyb* expression in homozygous embryos was reduced from 36 hours post-fertilization (hpf) in the AGM (Figure 1A, B) and was almost absent at 5 days post-fertilization (dpf) in the CHT (Figure 1I, J). Similarly, the expression of two other HSPC markers *runx1* as well as *scl* were also decreased (Figure 1K-N), suggesting the definitive HSPCs were impaired. ldd794 heterozygous fish was crossed with a Tg (*cmyb*:EGFP) homozygous individual (a stable zebrafish transgenic line expressing EGFP under the control of the *cmyb* promoter) [32]. The adult fishes carrying both *dnmt1* mutant allele and EGFP transgene were increased. As expected, the number of EGFP-positive cells was significantly decreased in the CHT of approximate 25% EGFP positive offspring at 4 dpf (Additional file 1: Figure S1A). This result further confirmed the HSPCs were specifically affected in ldd794 mutants.

The temporal and spatial expression patterns of a set of hematopoietic transcription factors and key genes involved in either lineage determination or differentiation were examined in ldd794 mutants. The expression of erythrocyte progenitor marker *gata1* [33], mature erythrocyte marker *hbae1* [34], myeloid-specific marker *mpx* [35], *l-plastin* [36] and *lysozyme C* [37], and lymphoid-specific marker *rag1* [38] were all diminished in ldd794 homozygous mutants (Figure 1O-Z). The decrease of multiple hematopoietic lineages suggested that the deficiency of hematopoietic precursors and/or progenitors occurred in the *dnmt1* mutants.

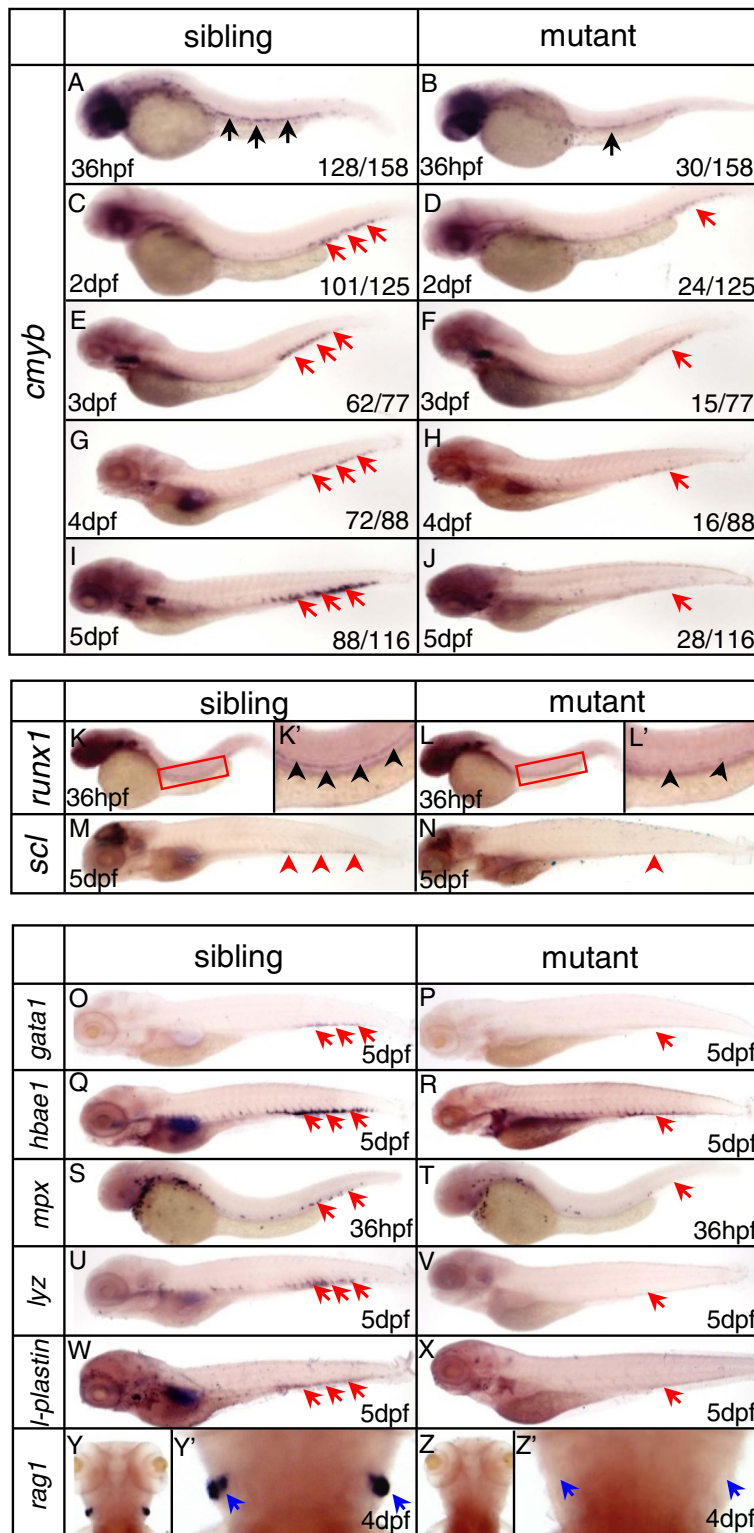

Figure 1 (See legend on next page.)

(See figure on previous page.)

Figure 1 Impairment of definitive hematopoiesis in *dnmt1* mutant zebrafish. (A-J) WISH analysis of *cmyb* expression from 36 hpf to 5 dpf. In ldd794 mutant, *cmyb* expression was decreased from 36 hpf (A-B) and absent at 5 dpf (I-J). (K, K', L, L') Expression of hematopoietic progenitor marker *runx1* was decreased at 36 hpf. (K', L') Magnified images of the boxed regions in K and L, respectively. (M-N) Expression of hematopoietic progenitor marker *scl* was decreased at 5 dpf. (O-Z) WISH analysis of key hematopoietic markers in *dnmt1* mutant embryos and wild-type siblings. Expression of erythrocyte progenitor marker *gata1* (O-P), mature erythrocyte marker *hbae1* (Q, R), myeloid-specific marker *mpx* (S, T), macrophage marker *lyz* (U, V), *l-plastin* (W, X) were decreased. Expression of lymphocyte maker *rag1* (Y, Y', Z, Z') was completely absent at 4 dpf. Blue arrows indicate the position of the thymus; red arrows indicate the CHT; black arrows indicate the AGM.

To exclude the possibility that the defective definitive hematopoiesis was due to the preexisting primitive hematopoietic defects in ldd794 mutants, a series of markers involved in primitive hematopoiesis, such as *scl*, *hbae1*, *pu.1*, *mpx*, and *lysozyme C* were also examined at 22 hpf. No overt changes have been detected (Additional file 1: Figure S1B), suggesting that primitive hematopoiesis was not affected in the *dnmt1* mutants.

Since normal vasculogenesis is required for the birth of HSCs from the ventral wall of the dorsal aorta in the zebrafish embryo [10,11,39,40], we evaluated early vascular development by expression of vascular markers. No obvious differences in *flk1* and *ephrinB2* expressions were observed between ldd794 siblings and mutants (Additional file 1: Figure S1C), suggesting that the vascular system and artery-vein differentiation remained intact and the hematopoiesis defects were not due to impaired vasculature.

Zebrafish ldd794 mutant encodes a truncated Dnmt1 lacking the enzymatic catalytic domain

Positional cloning approach was applied to identify the gene responsible for the defective definitive hematopoiesis in ldd794 mutants. Bulk segregation analysis indicated that the potential mutation site was located on chromosome 3. The 528 putative mutant embryos (1,056 meioses) were further examined. Seven homologous recombinations of *sslp1* (zC250L3) and eight homologous recombinations of *sslp2* (zC74M13) from different embryos were identified, which enabled us to localize the mutation to a 0.45-MB region containing eight genes (Figure 2A). Complementary DNA (cDNA) sequencing of all eight candidate genes revealed that in *dnmt1*, there was a T to A transversion, which introduced a stop codon at 743th amino acid, resulting in a predicted truncated Dnmt1 lacking the DNA methylation catalytic domain (Figure 2B-D). The gene synteny analysis revealed that Dnmt1 genomic context was highly conserved from zebrafish to human (Figure 2E).

Loss of Dnmt1 catalytic activity leads to specific HSPC defects

WISH analysis revealed that zebrafish *dnmt1* was expressed ubiquitously, including the hematopoietic regions (Additional file 1: Figure S2). The *dnmt1* specific antisense ATG-morpholino (MO) was injected into wild-

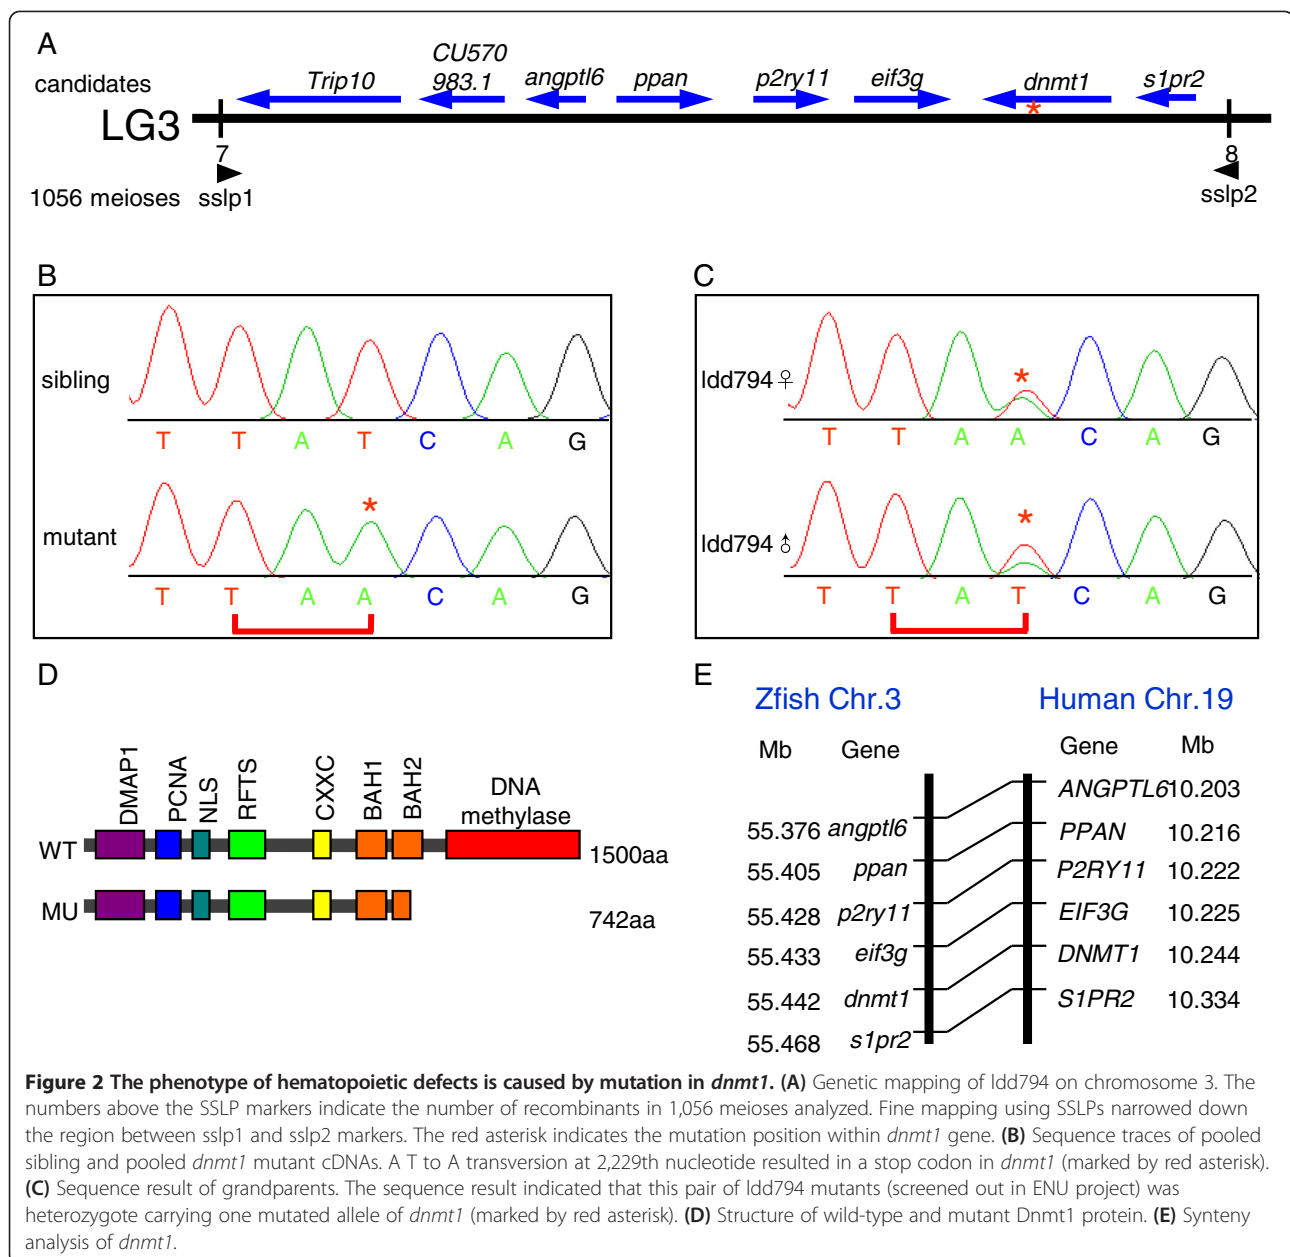

type embryos at one-cell stage to reproduce the phenotypes observed in ldd794 mutant embryos. As expected, the expression of *cmyb* diminished from 36 hpf (Figure 3B, B') in the AGM and significantly reduced in the CHT at 5 dpf (Figure 3E, E'), which was exactly a phenocopy of ldd794 mutants. Unsurprisingly, erythrocytes, myeloid cells, and lymphocytes were decreased in *dnmt1* ATG morphants (Additional file 1: Figure S3). Furthermore, a *dnmt1* splicing MO, specifically affecting splicing of precursor *dnmt1* RNA transcripts (Additional file 1: Figure S4), was also able to mimic the Dnmt1 protein truncation identified in ldd794 mutants. A similar effect to that of ATG MO was observed (Figure 3C, C'; G, G'), further confirming that the loss of Dnmt1 catalytic activity indeed specifically led to observed HSPC defects in the *dnmt1* mutants.

Finally, specific *in vivo* rescue experiments were carried out. Full-length zebrafish *dnmt1* mRNA was co-injected with *dnmt1* ATG MO into wild-type embryos. The results showed that *dnmt1* mRNA could efficiently rescue the hematopoietic defects in *dnmt1* morphants (Figure 3D, D'; H, H'). In contrast, co-injection of the truncated *dnmt1* mutant mRNA with the *dnmt1* ATG MO was ineffective (data not shown). Consistently, *dnmt1* mRNA could also restore the defects of HSPCs in ldd794 mutant embryos (Figure 3I-N). These data demonstrated that the phenotype observed in *dnmt1* mutants was indeed Dnmt1 dependent.

To investigate whether the observed deficient Dnmt1-mediated phenotypes were due to abnormal cell proliferation or apoptosis of definitive HSPCs, the anti-phosphorylated histone H3 (pH3) immunostaining and TUNEL assay were performed, respectively. A decrease of pH3 and *cmyb*-EGFP double positive cells was detected while no obvious change of TUNEL and *cmyb*-EGFP double positive cells was found in *dnmt1* mutants (Figure 3O-U, Additional file 1: Figure S5). Similar results were observed in *dnmt1* morphants (data not shown), suggesting that the defects of HSPCs in *dnmt1*-deficient embryos were caused by decreased proliferation.

Increased *cebpa* expression was correlated with hypomethylation of CpG islands

Given the fact that Dnmt1 predominantly methylates hemimethylated CpG dinucleotides in the mammalian

genome and facilitates repression in promoter regions, we speculate that the loss of Dnmt1 might activate some key negative regulators of definitive hematopoiesis.

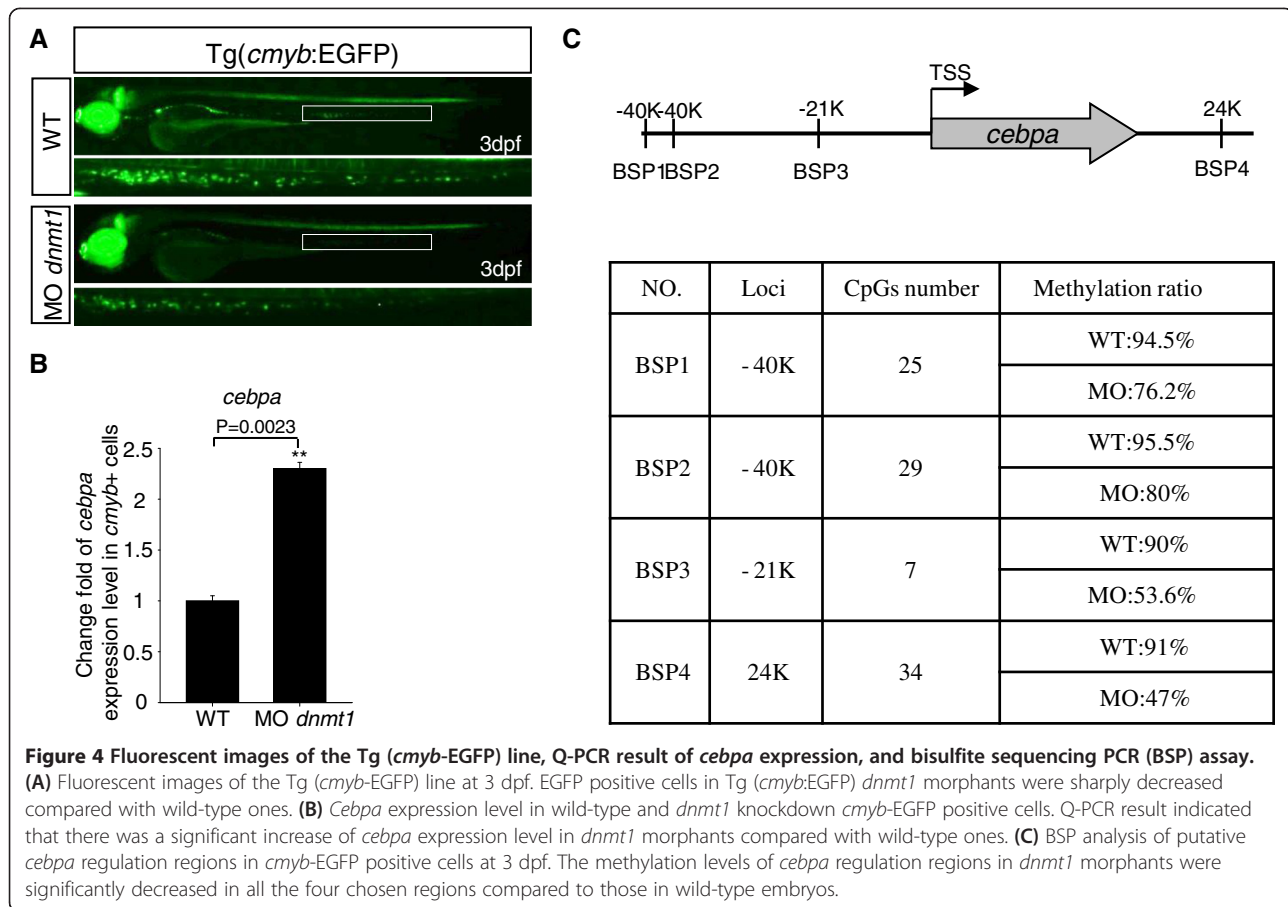

C/ebpa, a member of the basic leucine zipper protein family of transcription factors [41,42], not only plays a pivotal role in granulopoiesis [43] but also regulates the self-renewal and proliferation of HSPCs at a much earlier stage during mouse hematopoiesis [44-47]. *C/ebpa* deficiency leads to hyperproliferation and increased self-renewal capacity in both fetal and adult HSCs [44,45,47], while activation of *C/ebpa* is sufficient to repress stem cell capacities and proliferation of HSCs [46]. More direct evidence is that *C/EBPα* has previously been reported as a

cell-cycle inhibitor [48]. These evidences prompted us to test whether *C/ebpa* function was important for mediating the observed HSPC proliferation phenotypes in the *dnmt1* mutants.

Firstly, to test whether *cebpa* was upregulated in *dnmt1*-deficient HSPCs, *dnmt1* MO was injected into Tg (*cmyb*:EGFP) embryos at one-cell stage, then *cmyb*-EGFP positive cells were sorted and collected at 3 dpf (Figure 4A). RT-PCR results showed that the expression of *cebpa* indeed increased in *dnmt1*-deficient *cmyb*-EGFP positive cells (Figure 4B).

Secondly, we checked the DNA methylation status of the CpG islands located near the zebrafish *cebpa* gene.

Up to 40 kb long of upstream, the coding region, and the downstream genomic sequence of the zebrafish *cebpa* gene were searched for potential CpG islands. A total of 14 candidate CpG islands were found, and their DNA methylation statuses were evaluated by bisulfite sequencing analysis. The hypermethylation was found in four CpG island regions (BSP1 to BSP4) near the *cebpa* gene in wild-type *cmyb*-EGFP positive cells. As expected, a much lower methylation status was found in these four CpG islands in MO-injected *cmyb*-EGFP positive cells (Figure 4C, Additional file 1: Figure S6). Taken together, *cebpa* expression is likely regulated by Dnmt1 activity.

***Cebpa* upregulation was involved in the defective HSPC phenotypes in *dnmt1*-deficient embryos**

A series of rescue assays were carried out in order to verify whether elevated expression of *cebpa* is responsible for *dnmt1* mutant phenotype. In our previous work, two repressive forms of *C/ebpa* have been constructed [49], SUMO2-*C/ebpa*, mimicking the constitutively sumoylated form of *C/ebpa* and POZ-*C/ebpa*, mimicking the SUMO-mediated repressive form. The mRNAs of these two constructs were individually injected into the wild-type embryos with *dnmt1* ATG

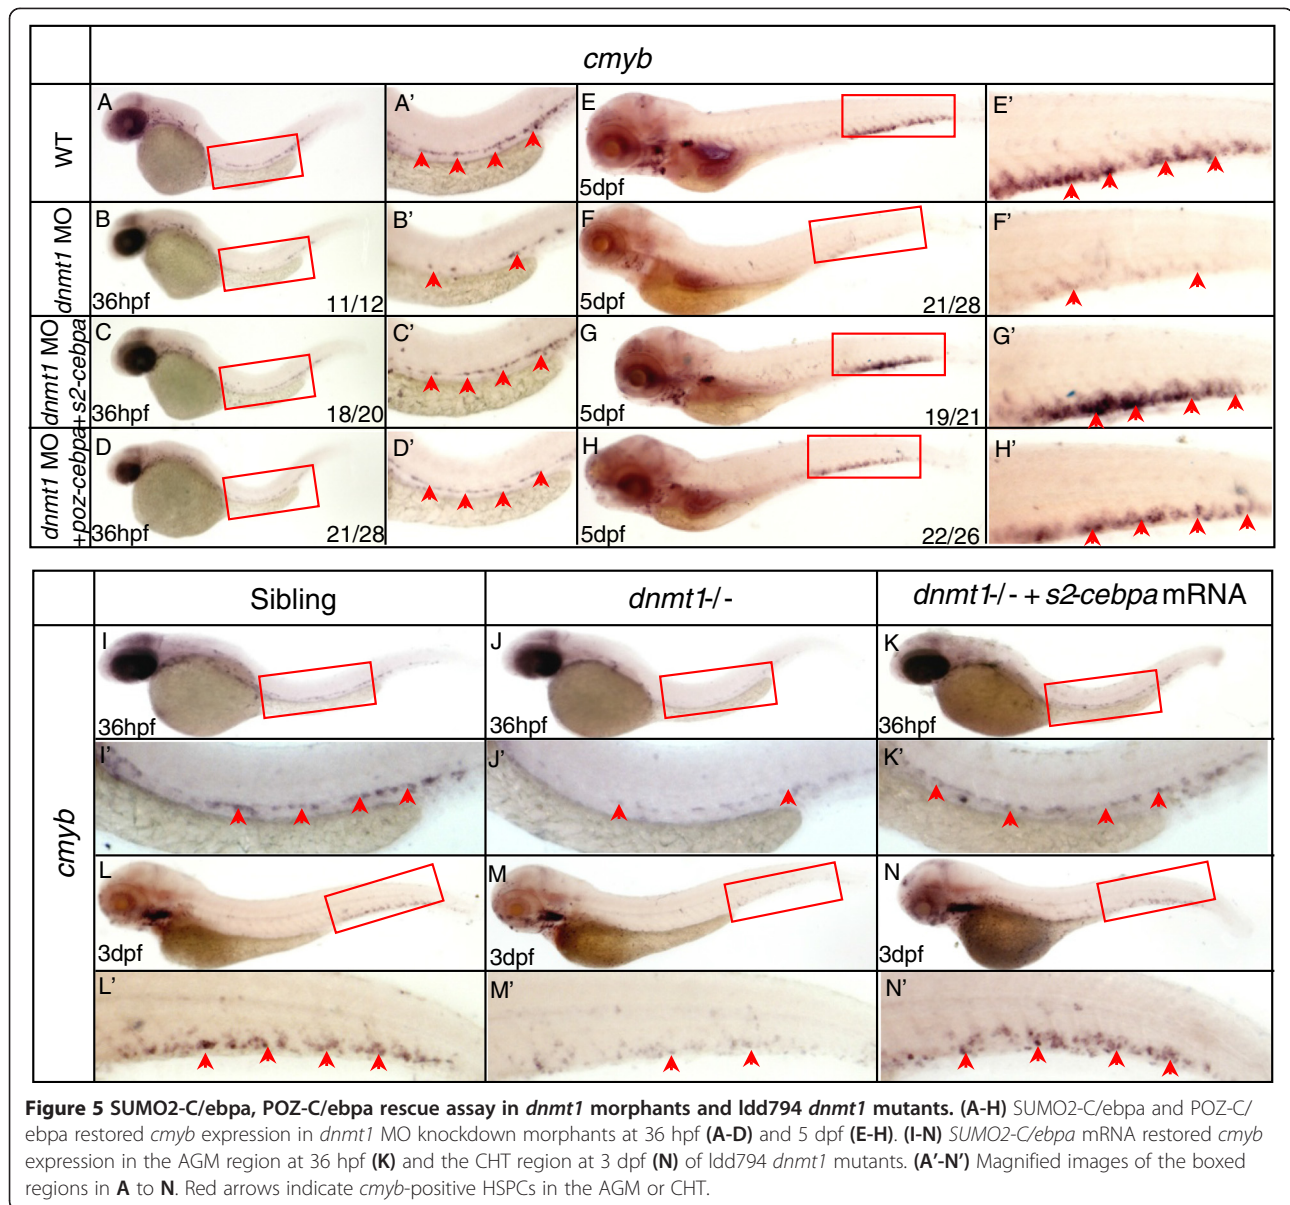

MO, respectively. Both were shown to be effective in rescuing *cmyb* expression (Figure 5A-H) in the morphants. The similar rescuing results were also observed in *ldd794* mutant embryos overexpressing SUMO2-*C/ebpa* repressive protein (Figure 5I-N).

It is worth noting that two *dnmt1* mutant lines with liver and pancreas development defects were reported [50]. As expected, the similar phenotypes were also detected in our *ldd794* mutants by assessing the expression of hepatocytes marker *lfabp* and pancreas marker *trypsin* (Additional file 1: Figure S7). Intriguingly, the rescue effects of SUMO2-*C/ebpa* on liver and pancreas development defects were not observed (Additional file 1: Figure S7), suggesting the role of Dnmt1 in liver and pancreas development was unlikely *cebpa* dependent.

Taken together, these data strongly suggest that elevated *cebpa* function is involved in HSPC defects of *dnmt1* mutants.

***Cebpa* function was pivotal to Dnmt1 regulated maintenance of definitive HSPCs**

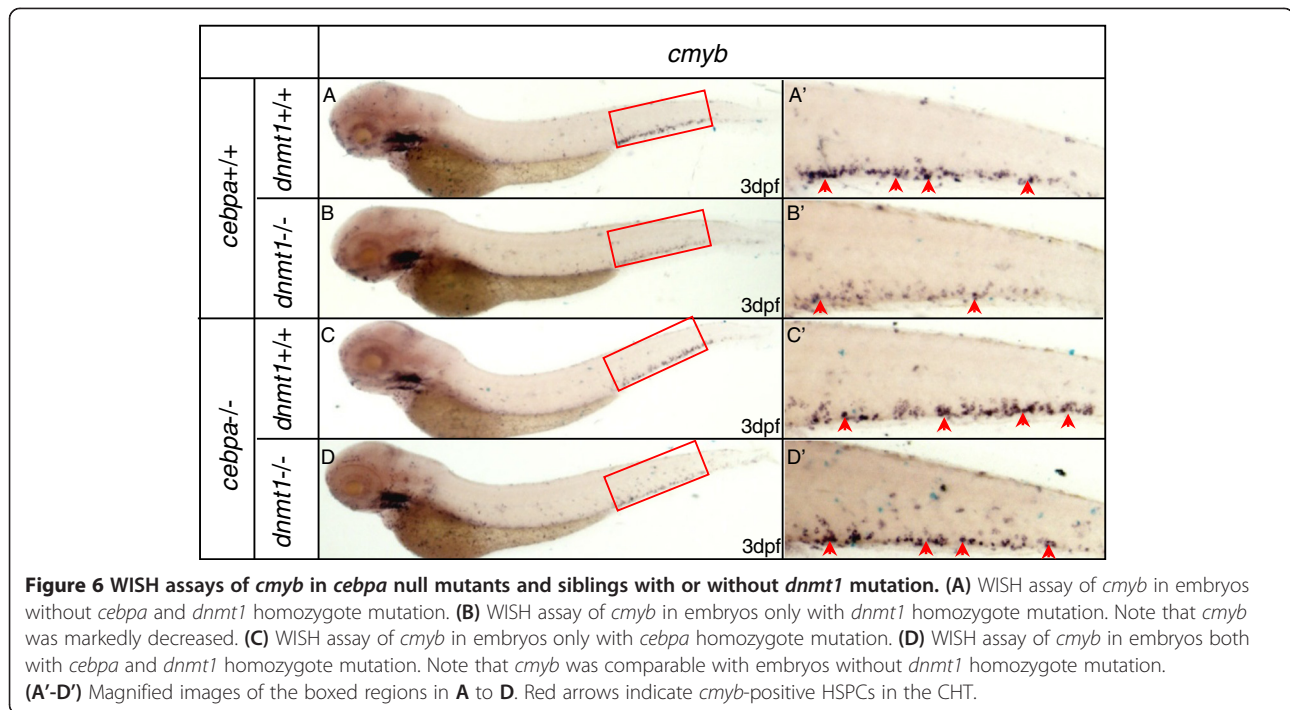

We have generated a *cebpa* null mutant zebrafish line by TALEN approach (submitted elsewhere). The phenotype was similar to that observed in mice. While no mature

myelocytes were detected by Sudan Black staining, the expression of *cmyb* remained unchanged, if not a marginal increase. This *cebpa* mutant line was then crossed with *ldd794* heterozygotes. The adult fishes carrying both *cebpa* and *dnmt1* mutant alleles were inbred. We found only in the presence of *C/ebpa* that *cmyb* expression was severely decreased (Figure 6B, B'). By contrast, in the *cebpa* and *dnmt1* double null mutants, the expression level of *cmyb* remained normal (Figure 6D, D'). In parallel, similar results were observed in *cebpa* null embryos knocked down with *dnmt1* MO (Additional file 1: Figure S8). These results indicate that the defective HSPCs triggered by *dnmt1* mutation require intact *C/ebpa* function. Therefore, *cebpa* is a key target gene of *dnmt1* and its regulated function is involved in the definitive HSPCs maintenance.

Discussion

In this study, a zebrafish mutant line with definitive hematopoiesis defects was identified. The specific phenotype was caused by a premature termination codon in the *dnmt1* gene, which resulted in a truncated Dnmt1 protein lacking its catalytic domain. DNMT1 protein is an important DNA methyltransferase to silence and regulate genes by methylation of DNA regions without changing the genomic DNA sequence [23]. Lack of Dnmt1 function resulted HSPC proliferation block and shortage of differentiated blood lineages. We demonstrated that normal Dnmt1 function was critical in regulating *cebpa* gene expression, and intact *C/ebpa* function was required for HSPC proliferation block triggered by the absence of Dnmt1 function. Our

studies provided new evidence for that *cebpa* is a downstream target of Dnmt1 in regulating HSPC proliferation during normal hematopoiesis.

Many lines of evidences demonstrate that DNA methylation influences gene expression during embryogenesis [51-53]. In mice, a *Dnmt1* mutation led to a recessive lethal phenotype with stunted and delayed development [24]. Similarly, two other zebrafish mutants related to *dnmt1* were shown to have defects in pancreas development at a late embryonic stage and resulted in embryonic lethality [50]. In line with these mutant phenotypes, our *ldd794* homozygous mutants usually die at 8 dpf with abnormal hematopoiesis and other organ formation such as the liver, further suggesting that reduced DNA methylation causes developmental abnormality and embryonic lethality. It is worth noting that *ldd794* heterozygotes do not display any observable phenotype, implying that the mutated *dnmt1* allele does not play a dominant negative role.

Our developmental and molecular analyses showed that the lack of Dnmt1 enzymatic activity in *ldd794* mutants led to severe reduction in HSPC numbers as well as impaired production of all three major lineages but accompanied by normal vascular development during early development. These observations are in an agreement with the ones from mouse studies [28]. Bone marrow transplant assays revealed that Dnmt1 affected HSCs in a cell-autonomous manner [28]. Our findings, together with those in mice, demonstrate that Dnmt1 has a conserved role in definitive hematopoiesis.

The phenotype with lower number of HSPCs in CHT might be due to either reduced proliferation or increased apoptosis of HSPCs. The pH3 and TUNEL assays suggested that the definitive HSPC defects are not due to increased apoptosis but likely caused by decreased proliferation of HSPCs. These results are also consistent with the fact that the frequencies of apoptotic cells in total BM, CMPs, GMPs, or MEPs remained unchanged in mouse mutants [28].

Given the fact that C/ebpa is a critical transcription factor for granulopoiesis [43], we have expected that its activation might induce accelerated myeloid differentiation. However, downregulated *mpx* expression in *dnmt1* mutant does not support an increased myeloid differentiation process. Meanwhile, an increased number of reports have demonstrated that C/ebpa is an important modulator of HSPC function [44-47]. Supporting this idea, we have found that hypomethylation of the *cebpa* regulatory region as a result of Dnmt1 deficiency is directly associated with HSPC impairment. Although the possibility of other negative regulators being activated cannot be excluded completely, HSPC proliferation defect caused by *dnmt1* mutation is indeed C/ebpa dependent; as in the *cebpa/dnmt1* double null mutants, the *cmyb* expression appeared to be normal. It was reported that C/EBPa negatively regulated *n-myc*, and the loss of C/EBPa resulted in de-repression of *n-myc* in mice HSCs [47]. Indeed, our Q-PCR analysis revealed that in *cmyb*-EGFP positive cells sorted from *dnmt1* MO knockdown embryos, *n-myc* had a much lower expression level (data not shown), which

might account for the pronounced decreased proliferation of HSPCs. Finally, one recent report revealed that a non-coding RNA arising from the *CEBPA* gene locus could influence the methylation level of *CEBPA* promoter by inhibiting DNMT1 protein binding to the regulatory region of *CEBPA* gene [54], which also supported our findings that Dnmt1 acts directly on *cebpa* promoter.

Taken together, our findings and others point out that the regulation of *C/ebpa* function during hematopoiesis takes place at multi-levels, including epigenetic modification, transcriptional regulation, and post-translational modification, which allow *C/ebpa* to exert its distinguished role in a fine-tuned manner.

Conclusions

Our studies for the first time clarify the possible molecular mechanism of Dnmt1 involved in HSPC maintenance during definitive hematopoiesis in zebrafish. The fact that *C/ebpa* functions as a critical downstream effector of Dnmt1 provides new insights of Dnmt1-regulated hematopoiesis.

Methods

Zebrafish maintenance and ENU mutagenesis

Zebrafish were maintained and staged under standard conditions as described previously [55]. Zebrafish embryos were cultured in “egg water” consisting of 0.03% sea salt and 0.002% methylene blue. A 0.0045% 1-phenyl-2-thiourea (Sigma-Aldrich, St. Louis, MO, USA) was used to prevent melanization and facilitate *in situ* hybridization analysis of gene expression [55]. ENU mutagenesis on Tubingen (Tu) strain was carried out as described [56]. The WIK line was used as the mapping strain. The zebrafish maintenance and study protocols were approved by the Institutional Review Board of the Institute of Health Sciences, Shanghai Institutes of Biological Sciences, Chinese Academy of Sciences (Shanghai, China).

Whole-mount *in situ* hybridization (WISH)

Digoxigenin (DIG)-labeled RNA probes were synthesized with T3 or T7 polymerase (Ambion, Life Technologies, Carlsbad, CA, USA), using linearized cDNA plasmid constructs. Whole-mount mRNA *in situ* hybridization was performed as described previously [57]. The DIG-labeled probes were detected using alkaline phosphatase-coupled anti-digoxigenin Fab fragment antibody (Roche, Basel, Switzerland) with BCIP/NBT staining (Vector Laboratories, Burlingame, CA, USA).

Mapping and positional cloning of *Idd794*

Idd794 (Tu background) carrying the mutant allele were outcrossed to the polymorphic wild-type strain WIK for positional cloning. The genome for linked SSLP (simple sequence length polymorphism) markers were scanned by

bulk segregation analysis using standard methods [58]. For fine mapping, *Idd794* mutant embryos were genotyped with SSLP markers to narrow down the genetic interval. The cDNAs of candidate genes were sequenced from pooled mutant RNA, and candidate mutation was confirmed by sequencing the genomic DNA of individual mutant embryo. All primers used for positional cloning and *dnmt1* sequencing are provided in Additional file 2.

Morpholinos and mRNA microinjection

Morpholinos (MOs) and mRNA were injected into embryos at one-cell stage. Morpholino oligonucleotides were designed by and ordered from Gene Tools. The morpholino sequences are as follows: for *dnmt1* MO, 5'-ACAATGAGGTCTTGGTAGGCATTTC-3' (4 ng/embryo) [27]; and for *dnmt1* splicing MO, 5'-CCACCCCTTCAAAA CAATAACAGTGT-3' (8 ng/embryo). Capped mRNA samples were transcribed from linearized plasmids (mMessage Machine; Ambion), purified, and diluted to 100 ng/ul (*dnmt1* and *dnmt1* mutant mRNA) or 50 ng/ul (*SUMO2-C/ebpa* and *POZ-C/ebpa* mRNA) for injection of embryos at one-cell stage.

Anti-phosphorylated histone H3 (pH3) immunostaining and TUNEL assay

Three days post-fertilization (dpf), Tg (*cmlyb:eGFP*) embryos were fixed in 4% paraformaldehyde (PFA). After dehydration and rehydration, the embryos were treated with Proteinase K (10 mg/ml) for 30 min at RT and re-fixed in 4% PFA for 20 min. After blocking with blocking buffer (2 mg/ml BSA+ 10% FBS + 0.3% Triton-X100 + 1% DMSO in PBST), the embryos were stained with mouse anti-GFP (Invitrogen, Carlsbad, CA, USA) and rabbit anti-phosphohistone H3 antibody (Santa Cruz) primary antibody at 4°C overnight. Alexa Fluor 488-conjugated anti-mouse (Invitrogen) and Alexa Fluor 594-conjugated anti-rabbit (Invitrogen) were used as secondary antibodies. Images were taken using Olympus FV 1000 confocal microscopy equipped with the FV10-ASW version 3 software.

Terminal transferase UTP nick end labeling (TUNEL) was performed using the *In Situ* Cell Death Detection Kit, TMR red (Roche), according to the manufacturer's recommendations.

Genomic DNA and RNA isolation

Tg (*cmlyb:EGFP*) embryos at one-cell stage were injected with *dnmt1* ATG morpholino. Cells positive for *cmlyb-EGFP* were sorted and collected from homogenized embryos at 3 dpf. Genomic DNA (gDNA) and total mRNA were extracted using the TRIzol reagent (Life Technologies) according to the manufacturer's instructions.

Quantitative real-time PCR

Reverse transcription was carried out using the super script first-strand synthesis system (Life Technologies) according to the manufacturer's instructions. Real-time quantitative PCR (Applied Biosystems, Foster City, CA, USA) was used for relative quantification of *cebpa* gene expression. The expression level of *cebpa* was normalized to the expression of housekeeping gene *GAPDH*. The primers used for real-time quantitative PCR were listed in Additional file 2.

Bisulfite sequencing PCR (BSP) assay

The DNA methylation assay was performed using the EZ DNA Methylation Kit (Zymo Research, Irvine, CA, USA) according to the manufacturer's recommendations. The treatment of DNA with bisulfite results in the selective conversion of unmethylated cytosine to uracil, whereas methylated cytosine remains unchanged. Methprimer (<http://www.urogene.org/methprimer/>) was used to predict the CpG islands. The following primers were used for bisulfite-specific polymerase chain reaction of the regulation regions of the *cebpa* gene: BSP1 Fw: 5'-GTTTATA GAAGTTTGTAGAGGGG-3' and Rv: 5'-AACAAACC CAACCTTCTTTATTAT-3'; BSP2 Fw: 5'-TTTTTTT TAGATGGTTTGTTTTAGG-3' and Rv: 5'-ATAAATT CACCCAAAATTCAAAC-3'; BSP3 Fw: 5'-TTTGA TAATTAGTATGAATTGTTTTGTTTT-3' and Rv: 5'-AACTTTAACCATATTATCCAAAATCACAT-3'; BSP4 Fw: 5'-ATATTTTTTGTGTAGATTTAAATGGTGTT-3' and Rv: 5'-TACTCCATATAACACATTTAATCCAA CTAA-3'. PCR products were subcloned into pMD18-T Vector (Takara, Kyoto, Japan), and transformed bacteria were cultured overnight. Clones (eight to ten) of each BSP were sequenced for confirmation.

Submit your next manuscript to BioMed Central and take full advantage of:

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution

Submit your manuscript at
