In studies in murine models, active suppression by IL-10-secreting Foxp3 regulatory T cells (Tregs) has emerged as an essential mechanism in colon homeostasis. However, the role of the equivalent subset in humans remains unclear, leading to suggestions that other subsets and/or mechanisms may substitute for Foxp3 Tregs in the maintenance of colon homeostasis. We recently described a new subset of CD4CD8 $\alpha\alpha$ T cells reactive to the gut bacterium *Faecalibacterium prausnitzii* and endowed with regulatory/suppressive functions. This subset is abundant in the healthy colonic mucosa, but less common in that of patients with inflammatory bowel disease (IBD). We discuss here the physiological significance and potential role of these Tregs in preventing inflammation of the gut mucosa and the potential applications of these discoveries for IBD management.

Keywords: Tregs, *Faecalibacterium prausnitzii*, IBD, microbiota, inflammation

DIVERSITY OF PERIPHERALLY DERIVED Tregs (pTregs)

CD4 regulatory T cells (Tregs) inhibit inflammatory responses (1). They can be subdivided into natural Tregs, which differentiate in the thymus (tTreg) and peripherally derived Tregs (pTregs), which differentiate in secondary lymphoid organs or tissues (2). These populations differ in terms of their non-redundant roles: tTregs play an essential role in maintaining tolerance toward self-structures, whereas pTregs are involved in the responses to externally delivered antigens or commensal microbes. Furthermore, the tTreg population appears to be stable, whereas that of pTregs may be more labile (3). This functional dichotomy results from differences in differentiation due to exposure to different TCR ligands (self and non-self antigens, respectively) and specific factors (cytokines, route of exposure, and antigen-presenting cells) in contrasting settings (4). The two Treg subsets can also be distinguished on the basis of the presence or absence of constitutive expression of the Foxp3 transcription factor. Constitutive Foxp3 expression and more particularly, the demethylation of a specific region of the Foxp3 locus are characteristic features of tTregs (5). Three main subsets of CD4 pTregs have been described in mice: Foxp3⁺CD25⁺ lymphocytes (3, 6), which are particularly abundant in the colon lamina propria (LP) (7) and two Foxp3⁻ subsets: the type 1 regulatory T (Tr1) cells and the T helper 3 (Th3) cells. The Tr1 subset secretes IL-10 and TGF- β in the absence of IL-4 and IL-17 (8–10) and is abundant in the small intestine (7). The Th3 subset may also secrete IL-10, but it differs from Tr1 in its expression of membrane-bound TGF- β (11, 12). The Tr1 Tregs are induced *in vitro* by IL-10 (8–10) and *in vivo* by TGF- β and IL-27 (9, 13) in the context of diverse immune responses (14) and upon chronic stimulation with antigens in the presence of IL-10 (10). The suppressive action of Tr1 Tregs is essentially IL-10-dependent, but it is also at least partly governed by TGF- β (8, 9). Moreover, the suppressive function of these cells may be

mediated by a cytotoxic mechanism dependent on granzyme B and perforin (15). The Th3 subset is induced in the gut mucosa by oral immunization (12, 13). Its suppressive effects are essentially mediated by TGF- β , but also partly by IL-10 (11, 16). Much remains unknown about the typical features of Tr1 and Th3 cells and their relative contributions to immune regulation in general and to gut homeostasis in particular. Recent studies have shown that the development of colonic Foxp3⁺ Tregs in mice is induced by gut clostridial bacteria and their metabolites, and that these Tregs play a key role in the prevention of colitis (17, 18). In humans, however, the role of gut Foxp3⁺ Tregs in irritable bowel disease (IBD) remains unclear (19, 20), leading to suggestions that these cells may be less crucial in humans than in mice for the maintenance of colon homeostasis (21, 22).

HUMAN COLON DP8 α T CELLS ARE pTregs INDUCED BY CLOSTRIDIAL BACTERIA

We recently reported that the CD4CD8 $\alpha\alpha$ (DP8 α) lymphocytes of the colon LP are Foxp3⁻ IL-10-secreting Tregs highly skewed toward the recognition of *Faecalibacterium prausnitzii*, a gut bacterium belonging to cluster IV of the genus *Clostridium* (23). In the healthy colonic mucosa of colon cancer patients, these cells account for about 12% of the CD4 lymphocytes present. We have shown that about 2% of the CD4 PBLs have the same CD4CD8 $\alpha\alpha$ phenotype and that 15% of these cells, on average, also react with *F. prausnitzii* (23). Together with the role of clostridial antigens in the induction of mouse colonic Tregs (17, 24) and the demonstration that segmented filamentous bacteria (SFB) antigens induce Th17 lymphocytes in the small intestine (25), our data suggest that *F. prausnitzii* participates in the induction of human DP8 α colonic Tregs through antigen presentation. Support for this hypothesis is provided by our recent observation that *F. prausnitzii* imprints a phenotypic tolerogenic profile including a failure to secrete IL-12 on LPS-matured human DCs *in vitro* (unpublished data). Interestingly, *F. prausnitzii* is the most abundant bacterium of the human intestinal microbiota in healthy adults (26, 27) and decreases in its abundance have been linked to dysbiosis in IBD (28–32). The unique anti-inflammatory potential of this bacterium has recently been demonstrated, both *in vitro* and *in vivo* (33, 34). We found that there were fewer DP8 α Tregs in the inflamed colonic mucosa and blood of Crohn's disease patients and in the blood of ulcerative colitis (UC) patients than in healthy individuals (23). These results suggest that lower levels of *F. prausnitzii* are associated with lower levels of *F. prausnitzii*-specific Treg anti-inflammatory activity in IBD patients, and that this may contribute to the disease. As a corollary, this suggests that DP8 α Tregs may play a role in colon homeostasis and IBD prevention. However, this hypothesis requires confirmation and a number of important questions about these cells remain to be answered, to define more precisely their contribution to IBD prevention.

DP8 α Treg: A NEW pTreg SUBTYPE

We must first consider whether DP8 α lymphocytes represent a new pTreg subtype. If Tr1 cells are defined as Foxp3⁻ Tregs

secreting IL-10, then DP8 α T cells could be considered to be Tr1 cells. Gagliani et al. (35) have suggested that human and mouse Tr1 cells are defined by the coexpression of CD49b and LAG3. We have also reported the expression of LAG3 by colonic DP8 α cells *ex vivo* (23), but we did not consider their expression of CD49b. Nevertheless, our data revealed significant differences between Tr1 cells and DP8 α Tregs. For example, DP8 α Tregs stably express the CD8 $\alpha\alpha$ homodimer, CD25 and the transcription factor GATA-3, but do not express PD1, considered to be a canonical marker of Tr1 cells (9, 35). Moreover, whereas suppression by Tr1 and Th3 Tregs is largely dependent on IL-10 or TGF- β secretion, respectively (7, 9), the inhibition of T-cell proliferation by DP8 α Tregs *in vitro* was little affected by a blocking anti-IL-10 antibody and not at all affected by an anti-TGF- β receptor antibody (23). It is, therefore, possible to distinguish DP8 α Tregs from the Tr1 and Th3 Treg subsets.

One surprising finding of our work is the lack of Foxp3 expression by DP8 α Tregs. However, they otherwise strongly resemble mouse Foxp3 colonic Tregs in terms of their regulatory markers (CD25, CTLA-4, GITR, and LAG3), regulatory functions (inhibition of T-cell proliferation, inhibition of DC maturation, and IL-10 secretion) and induction by related clostridial species (23). In both mice and humans, Foxp3 expression is required to maintain the Treg cell program and suppressive functions of tTreg (36) by repressing the activation-dependent expression of a number of genes, as elegantly shown in a recent study (37). In mice, Foxp3 is also expressed by the pTregs induced by clostridial bacteria (17). We have reported that DP8 α Tregs have highly stable regulatory properties (23). This implies a high degree of commitment of these cells to their Treg status, with the expression of a Foxp3-independent genetic program in these cells. We are currently trying to decipher the genetic basis of DP8 α Treg commitment by comparing the transcriptomic signatures of the three main subtypes of CD4 lymphocytes in the colon LP: DP8 α Tregs, conventional CD4 (CD4⁺CD25⁻CD127^{High}), and Foxp3 Tregs (CD4⁺CD25⁺CD127^{Low}), with and without activation.

COLONIC DP8 α Tregs: FUNCTIONAL HOMOLOGS OF THE pTregs INDUCED BY CLOSTRIDIAL BACTERIA IN MICE?

One important question raised by our results is whether human DP8 α Tregs are functional homologs of the mouse Foxp3 Tregs induced by clostridial species (17), as shown in **Figure 1**. Alternatively, clostridial bacteria might induce both Treg subsets, with these subset playing complementary roles in colon homeostasis. This second hypothesis is unlikely in mice, because most of the IL-10-secreting Tregs of the colon LP express Foxp3, so IL-10-secreting Foxp3-negative lymphocytes are missing from this compartment (7). CD4CD8 $\alpha\alpha$ IL-10-secreting T lymphocytes have been described in the mouse gut mucosa. However, these cells were located in the epithelium of the small intestine (38), a compartment clearly different from the colon in terms of the composition and function of its immune components (39). In addition, we found no reactivity to *F. prausnitzii* in freshly sorted human colonic Foxp3 Tregs, suggesting

that this bacterium (or at least its antigens) is not involved in the induction of Foxp3 lymphocytes in the human colon LP (unpublished data). This may appear to conflict with the induction of Foxp3 Treg development by human clostridial bacteria in the colonic mucosa of GF mice (24), but the true meaning of this result remains unclear, because another study has shown that the human microbiota cannot restore normal mouse colon development upon transfer into GF animals (40). It, therefore, appears possible that during evolution, both humans and rodents have selected clostridial symbionts on the basis of their capacity to maintain colon homeostasis via Treg induction, but that these two groups diverged in terms of the molecular mechanisms involved in this process. Consistent with the hypothesis that DP8 α Tregs may be functional homologs of mouse Foxp3 pTregs, the role of human Foxp3 Tregs in the prevention of colitis remain unclear (19). Moreover, the manifestations of enteropathy in IPEX (immune dysregulation, polyendocrinopathy, enteropathy, X-linked syndrome) patients (who lack functional Foxp3 Treg), which are often considered to provide support for a role for Foxp3⁺ Tregs in the prevention of IBD, clearly differ from those in IBD (41). This suggests that IPEX-associated colitis results from autoimmune attacks rather than from defects in tolerance to the microbiota and, thus, that mechanisms other than Foxp3 Treg-dependent suppression, possibly

including suppression by DP8 α Tregs, are involved in human colonic homeostasis (21, 22).

ARE ALL BLOOD DP8 α LYMPHOCYTES REGULATORY T CELLS?

About 2% of CD4 PBLs have the same double-positive phenotype as DP8 α LPLs, raising questions about their function. Most DP8 α PBLs lacked regulatory markers *ex vivo*, but they acquired these markers and regulatory functions after a short period of *in vitro* activation or establishment in culture (which also requires TCR activation), whereas their CD4 homologs did not. Moreover, *ex vivo*, about 10% of DP8 α PBLs expressed the gut homing receptor CCR9, and about the same proportion recognized *F. prausnitzii* (23). Therefore, most DP8 α PBLs appear to be Tregs, although only a limited fraction of these cells react to *F. prausnitzii*. It is possible that some of these cells are pTregs induced by microbiota components present outside the gut, in the pulmonary mucosa, or the skin, for example. It is also possible that some of the circulating DP8 α lymphocytes are not Tregs. Additional studies will be required to address these questions and to determine the specificity of the TCRs of regulatory DP8 α PBLs that do not recognize *F. prausnitzii*.

DOES THE CD8 α MOLECULE PLAY A ROLE IN DP8 α Treg FUNCTION?

CD8 α expression can be transiently induced on human CD4⁺ T lymphocytes by activation in the presence of IL-4 (42). However, this molecule is expressed constitutively by the DP8 α lymphocytes of the human colon LP and blood (23). This raises questions about the possible role of this molecule in DP8 α Treg function. Like the CD8 α β coreceptor, CD8 α binds to MHC class-I molecules (43). In mice and humans, it also binds to the specific ligands thymus leukemia antigen (TL) (44) and gp180 (CEACAM5)/CD1d (45, 46), respectively. The human CD8 α ligand is expressed in the gut, by non-lymphoid cells, such as colonic epithelial cells and polynuclear neutrophils, two types of non-professional APCs that can activate MHC class II-restricted T lymphocytes. Previous studies have shown that the interaction between the CD8 α molecule and its ligands costimulates both the TCR activation induced by specific MHC/Ag complexes or by CD3 antibody, and T-cell function (44, 47). Moreover, CD8 α has been shown to play a role in the selection of high-affinity CD8 α β T cells (48). We have observed (unpublished data) that the

triggering of CD8 α by an anti-CD8 antibody (OKT8) enhances the activation of DP8 α Tregs induced by an anti-CD3 antibody (OKT3). This suggests that ligation of the CD8 α molecule of DP8 α Tregs may increase their TCR-dependent activation by microbiota-derived antigens. It has recently been shown that TCR signaling is critical for the maintenance of the suppressive capacity of Foxp3 Tregs in mice, particularly in the colonic mucosa (49). It would be interesting to determine whether there is a similar dependence on TCR signaling in DP8 α Tregs and whether the CD8 α receptor contributes to this process.

DP8 α Tregs, BIOLOGICAL MARKERS AND THERAPEUTIC TARGETS IN IBD

Our observation that DP8 α Treg levels are low in the colonic LP and blood of IBD patients, who frequently also have low levels of *F. prausnitzii* in their gut microbiota, provides evidence in support of a correlation between the levels of these bacteria and DP8 α Treg levels in these patients (Figure 2). As recently suggested (50), such a correlation might result from a feedback loop between the selection, by follicular regulatory T cells (Tfr), of an adequate

IgA repertoire fostering microbiota diversity, particularly as concerns the abundance of clostridial bacteria, which in turn govern the development or survival of DP8 α Tregs. In this context, the possible presence of DP8 α Tfr should be investigated.

It is currently difficult to determine whether there is a strong correlation between the levels of DP8 α Tregs and *F. prausnitzii* in the colonic mucosa, as no method for quantifying DP8 α lymphocytes in biopsy specimens is available. There is an urgent need to develop such a method, based on CD4 and CD8 α colabeling by immunohistochemistry, although this approach would not distinguish between CD4CD8 $\alpha\alpha$ and CD4CD8 $\alpha\beta$ lymphocytes, or, preferentially, quantitative RT-PCR, if a specific marker of colonic DP8 α lymphocytes can be identified from the transcriptomic signature of these cells. Efforts are currently being made to identify such a marker.

Only about 15% of DP8 α PBLs appear to be specific for *F. prausnitzii*, suggesting that the remaining circulating DP8 α lymphocytes are not induced by the gut microbiota. Nevertheless, the total frequency of DP8 α PBL and the frequency of these cells for *F. prausnitzii* are lower in the blood of IBD patients than in controls (23). The question as to whether the frequency of circulating DP8 α lymphocytes and/or of DP8 α lymphocytes reactive to *F. prausnitzii* can be viewed as a biological marker of IBD is an important issue as there are currently no specific biomarkers of this disease. It will be necessary to determine whether DP8 α levels are correlated with disease type and activity and predict

disease progression in a large cohort of IBD patients to answer this question.

If DP8 α levels in the blood or the colonic mucosa are found to be predictive of disease progression, this would provide an objective means of assessing the contribution of these Tregs to the prevention of IBD. Such an advance would open up new possibilities for treating IBD by manipulating the frequency of *F. prausnitzii* in the gut microbiota or increasing the number of circulating DP8 α Tregs through specific *in vivo* stimulation or induction, or adoptive transfers of these cells. We have found that DP8 α Tregs proliferate well *in vitro*, whilst maintaining their regulatory phenotype and functions (23).

CONCLUDING REMARKS – FUTURE ORIENTATIONS

We have identified, for the first time in humans, a mechanism by which the gut microbiota can affect gut homeostasis: the induction of DP8 α Tregs in a mucosa exposed to frequent stimulation with microbiota-derived immune stimuli, both PAMPs and microbe antigens. The precise physiological significance of DP8 α Tregs remains to be determined, but the discovery of these cells has potentially wide-ranging implications for the management of IBD and, potentially, of other immune diseases involving the abnormal induction and/or function of microbiota-induced DP8 α Tregs.
