BK polyomavirus (BKPV) frequently reactivates in kidney transplant recipients with immunosuppressive regimen and triggers BKPV-associated nephropathy (BKPVAN) and graft rejection. Determining effective risk factors for BKPV reactivation is required to achieve efficient prevention.

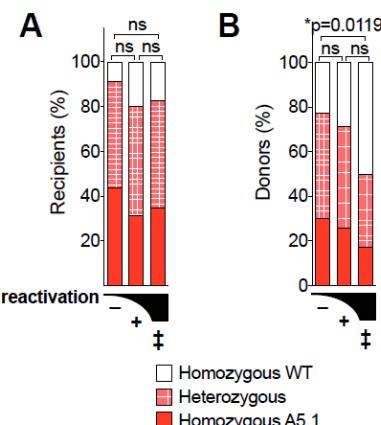

We show that, in kidney, MHC class I related chain A (MICA) is predominantly expressed in tubule epithelial cells, the natural targets of BKPV, questioning a role for MICA in the immune control of BKPV infection.

MICA (green) polarizes at the apical side of the tubule epithelium

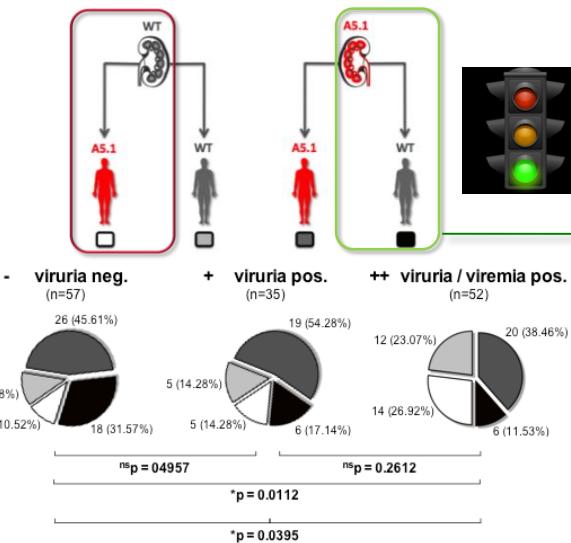

Focusing on *MICA* genotype we found a lower incidence of BKPV reactivation in recipients transplanted with renal graft carrying *MICA* A5.1 mutant, encoding a truncated non-conventional MICA protein.

Study cohort: **144 kidney transplant donor/recipient pairs** including recipients with no reactivation (controllers), mild (virurics) or severe (viremics) BKPV reactivation post-graft.

Donor/Recipient Mismatch for MICA A5.1 impacts on BKPV outcome

We established that a **mismatch for *MICA* A5.1 between transplant donor (D) and recipient (R) is critical for BKPV reactivation and BKPVAN**. Functionally, we associated a low prevalence of BKPV reactivation with **elevated anti-MICA sensitization** and **reduced plasma level for soluble MICA (sMICA)** in recipients, two potential effector mechanisms resulting from MICA A5.1 mismatch that may improve infection outcome.

Hypothesis
