1 Abstract

The transcription factor E2F1 plays a key role during S phase progression and apoptosis. It has been well-demonstrated that the apoptotic function of E2F1 involves its ability to transactivate pro-apoptotic target genes. Alternative splicing of pre-mRNAs also plays an important role in the regulation of apoptosis. In this study, we identify the splicing factor SC35, a member of the Ser-Rich Arg (SR) proteins family, as a new transcriptional target of E2F1. We demonstrate that E2F1 requires SC35 to switch the alternative splicing profile of various apoptotic genes such as c-flip, caspases-8 and -9 and Bcl-x, towards the expression of pro-apoptotic splice variants. Finally, we provide evidence that E2F1 upregulates SC35 in response to DNA damaging agents and show that SC35 is required for apoptosis in response to these drugs. Taken together, these results demonstrate that E2F1 controls pre-mRNA processing events to induce apoptosis and identify the SC35 SR protein as a key direct E2F1-target in this setting. Keywords: Alternative splicing/Apoptosis/E2F1/SC35/SR proteins

1 Introduction

2

3 Pre-mRNA splicing is an essential step for the expression of most genes in higher 4 eukaryotic cells. This process has emerged as an important mechanism of genetic diversity since 5 about 74% of human genes undergo alternative splicing, leading to the production of various protein isoforms¹. SC35 belongs to the serine/arginine-rich (SR) protein family, one of the most 6 7 important class of splicing regulators. Members of the SR family have a modular structure 8 consisting of one or two copies of an N-terminal RRM (RNA-recognition motif) followed by a C 9 terminus rich in serine and arginine residues known as the RS domain. They act at multiple steps of spliceosome assembly and participate in both constitutive and alternative splicing 2 . Together 10 11 with most of the other splicing factors, SR proteins localize to nuclear subregions termed nuclear speckles³. Extensive serine phosphorylation of the RS domain plays an important role in the 12 regulation of both the localization and the activities of SR proteins⁴. While the splicing functions 13 14 of SR proteins have been well documented "in vitro", their roles and physiological targets "in 15 vivo" are less well known. However, based on gene targeting experiments demonstrating that 16 they are required for cell viability and/or animal development, SR proteins undoubtedly control 17 essential biological functions.

Apoptosis is one of the cellular processes in which alternative splicing plays an important regulatory role. Indeed, a remarkable number of transcripts that encode proteins involved in the apoptotic pathway are subjected to alternative splicing. This usually drives the expression of proteins with opposite functions, either pro- or anti-apoptotic ⁵. Interestingly, changes in SR protein phosphorylation have been observed upon apoptotic stimulation following activation of the Fas receptor ⁶. In addition, "*in vitro*" overexpression experiments have suggested a potential

role for SR proteins in the control of the splicing of pre-mRNAs encoding apoptotic regulators ⁷⁻
⁸. Moreover, depletion of the ASF/SF2 SR protein has been reported to induce apoptosis ⁸⁻⁹.
Nevertheless, whether individual SR proteins are necessary to modulate alternative splicing of mRNAs encoding apoptotic factors remains largely unknown, as well as the factors that control expression and/or activity of SR proteins in this context.

6 The E2F1 transcription factor belongs to the E2F family encompassing eight members involved in a diverse array of essential cellular functions ¹⁰. E2F1 is best-known for its role in 7 8 driving cell cycle progression in S phase. In addition, E2F1 can induce apoptosis by mechanisms 9 involving or not its transcriptional function. We previously demonstrated the ability of E2F1 to 10 trigger apoptosis through caspase-8 activation at the death-inducing signaling complex and 11 showed that E2F1 acts through specific downregulation of the cellular FLICE-inhibitory protein short isoform, c-FLIP_{short}¹¹. As *c-flip* predominantly encodes two isoforms arising from 12 alternative splicing, namely c-FLIP_{short} and c-FLIP_{long}, we postulated that E2F1 could control the 13 14 expression and/or activity of some splicing factors. In this study, we identify the SC35 splicing 15 factor as a direct transcriptional target of E2F1 and show that SC35 is involved in the ability of 16 E2F1 to trigger apoptosis through downregulation of c-FLIP_{short}. Importantly, we demonstrate 17 that E2F1 and SC35 also cooperate to switch the alternative splicing pattern of *caspases*-8 and -9 as well as of Bcl-x, towards the expression of pro-apoptotic isoforms. Finally, we provide 18 19 evidence that E2F1 promotes the accumulation of SC35 in cells treated with DNA damaging 20 agents, and show that SC35 is required for induction of apoptosis in this setting. Taken together, 21 these results demonstrate that E2F1 and SC35 proteins control pre-mRNA processing events to 22 promote apoptosis.

1 **Results**

2

3 E2F1 upregulates SC35 protein expression

4 We previously established a model of stable E2F1-inducible clones in the H358 cell line derived from a human lung adenocarcinoma¹¹. Here we exploit this model to test whether E2F1 5 6 can control the expression pattern of three members of the SR protein family, one of the most 7 important class of splicing regulators, namely SC35, SRp20 and SF2/ASF. Immunoblotting 8 experiments demonstrated a 3-4 fold increased expression of SC35 in cells overexpressing E2F1, 9 whereas the total level of SRp20 and SF2/ASF was not affected (Figure 1A, left panel). This 10 effect required the DNA binding activity of E2F1 since overexpression of an E2F1(E132) DNA-11 binding defective mutant did not affect SC35 protein level (Figure 1A, right panel).

12 To confirm these data, we knocked-down E2F1 expression by using small interfering 13 RNAs (siRNAs) in the H69 and H810 neuroendocrine lung carcinoma cell lines that 14 physiologically express high levels of E2F1, and analyzed SC35, SRp20 and SF2/ASF expression 15 by western blotting. As shown in figure 1B, the silencing of E2F1 was accompanied by marked 16 downregulation of the endogenous SC35 protein in both cell lines as compared to cells 17 transfected with *mismatch* siRNA. In contrast, the expression of SRp20 and SF2/ASF proteins 18 was not affected. In addition, we observed that SC35 protein levels were strongly reduced in 19 E2F1 knock-out MEF as compared to wild-type MEF, whereas those of SRp20 and SF2/ASF did 20 not change (Figure 1C). Taken together, these data demonstrate that SC35 expression is 21 positively regulated by E2F1.

22

1 SC35 is a direct transcriptional target of E2F1

2 To test whether E2F1 controls SC35 expression at the transcriptional level, we performed 3 RT-PCR experiments using primers localized at the 5'-end of the sc35 ORF. The data showed 4 that expression of sc35 mRNA was induced by E2F1 but not by the mutant E2F1(E132) (Figure 5 2A). To go further, we performed Chloramphenicol Acetyl Transferase (CAT) experiments using 6 a pR264-CAT plasmid that contains the 1kb human sc35 promoter upstream of CAT cDNA 12 . 7 Co-transfection of H1299 (Figure 2B) or SAOS2 (data not shown) cells with pR264-CAT vector 8 and increasing amounts of an E2F1 expression vector resulted in a dose-dependent increase of 9 CAT activity. These results indicated that E2F1 can transactivate the promoter of sc35. To 10 confirm these data "in vivo", we performed chromatin immunoprecipitation (ChIP) experiments 11 in the H358/Tet-On/E2F1 cells cultured in the presence of doxycylin (Figure 2C, upper panel). 12 As a positive control of ChIP assays, we used the proximal human Skp2 promoter that was recently reported as a target of E2F1 13 . In our conditions, binding of E2F1 to the proximal *Skp2* 13 14 gene promoter was clearly detected whereas no binding was observed with the Gapdh promoter 15 (Figure 2C, upper panel). Importantly, the sc35 promoter fragment (-296/-79) that encompasses 16 two putative E2F1 binding sites was precipitated by an anti-E2F1 antibody (Figure 2C, upper 17 panel). In order to confirm that SC35 was a direct target of E2F1, endogenous E2F1 was 18 immunoprecipitated from H1299 cells and ChIP experiments were performed. As shown (Figure 19 2C, lower panel), endogenous E2F1 clearly bound to the sc35 promoter in these cells. Taken 20 together, these results identify *sc35* as a direct transcriptional target of E2F1.

1 E2F1 promotes SC35-dependent apoptosis through modulation of FLIP_{long}/FLIP_{short}

2 ratio

3 As we previously demonstrated the ability of E2F1 to induce apoptosis through downregulation of the c-FLIP_{short} protein isoform ¹¹, we next analyzed whether SC35 plays a role 4 5 in this setting. By the use of sc35 siRNAs and Hoechst staining, we firstly observed that 6 neutralization of SC35 strongly reduced the number of apoptotic cells in response to E2F1 7 (Figure 3A). Therefore, these results indicated that SC35 is required for E2F1-induced apoptosis. 8 Importantly, RT-PCR (Figure 3B, left panel) and immunoblot analyses (Figure 3B, right panel) 9 revealed that downregulation of both *flip_{short}* mRNA and protein levels was also prevented in 10 these conditions. A high level of both c-FLIP protein isoforms has been found in many tumor 11 cells and was correlated with resistance to FAS- and TRAIL-induced apoptosis, two death receptor ligands ¹⁴. Consistently, we previously reported that the downregulation of c-FLIP_{Short} 12 by E2F1 was sufficient to restore the sensitivity of tumor cells to these ligands ¹¹. In this study, 13 14 we showed that neutralization of sc35 expression overrode the ability of E2F1 to sensitize H358 cells to FasL (Figure 3C) as well as to TRAIL (data not shown) treatments. Collectively, our data 15 demonstrate that E2F1 induces apoptosis through SC35-dependent modulation of the FLIPLong 16 17 /FLIP_{Short} ratio, at the expense of the FLIP_{Short} protein isoform.

18

E2F1 and SC35 co-regulate the splicing pattern of *caspase-8*, *caspase-9* and *Bcl-x* pre-mRNAs in favor of pro-apoptotic splice variants

As the expression of numerous apoptotic genes is regulated by pre-mRNA alternative splicing ⁵, we undertook a series of experiments to test whether E2F1 and SC35 can also affect the ratio of other apoptotic splice variants. Various *caspases* are subjected to alternative splicing.

Alternative splicing of casp-2 proceeds through selective insertion or removal of exon 9 giving 1 rise to anti-apoptotic caspase-2S and pro-apoptotic caspase-2L isoforms-respectively⁷. The use 2 3 of a distant splice donor site at the 3'-end of exon 8 of human caspase-8 pre-mRNA leads to the synthesis of an alternative splice variant, *caspase-8L*, a competitive inhibitor of caspase-8¹⁵⁻¹⁶. 4 5 The inclusion or exclusion of an exon cassette in *caspase-9* causes the expression of two splice variants, namely the pro-apoptotic *caspase-9a* and anti-apoptotic *caspase-9b*¹⁷⁻¹⁸. To assess 6 7 whether E2F1 induces changes in the alternative splicing profile of these *caspases* pre-mRNAs, 8 RNAs recovered from non-induced or induced H358/Tet-On/E2F1 cells were analyzed by RT-9 PCR using primers specific for each caspase splice variant (Figure 4A). The results showed that 10 E2F1 increased the expression of pro-apoptotic *caspases-2L*, -8a and -9a mRNA levels and 11 decreased those of anti-apoptotic *caspases-8L* and -9b (Figure 4B). In contrast, these effects were 12 not observed with mutant E2F1(E132). Interestingly, we were unable to detect the caspase-2S 13 transcript in our cells. Altogether, these data indicate that E2F1 can switch the splicing pattern of caspases-8 and -9 in favor of pro-apoptotic isoforms. Therefore, besides its ability to 14 transactivate *caspases*-8 and -9 genes ¹⁹, E2F1 also controls their alternative splicing. 15

16 Bcl-x is a member of the bcl-2 gene family that also plays a key role in apoptosis. Several 17 splice isoforms of Bcl-x have been reported. The use of a 5' proximal site generates the Bcl-x_L long isoform which protects cells against apoptosis. In contrast, the use of a 5' distal site results 18 in the synthesis of a short pro-apoptotic Bcl- x_S isoform 20 . To analyze whether E2F1 regulates 19 20 the splicing pattern of Bcl-x, we performed RT-PCR analysis with specific primers in H358/Tet-21 On/E2F1 cells (Figure 4A). The results showed that expression of E2F1 induced a concomittant 22 decrease of $Bcl-x_L$ and increase of $Bcl-x_S$ mRNA levels (Figure 4C, upper panel). As was 23 observed for *caspase* regulation, the mutant E2F1(E132) had no effect on *bcl-x* splicing. Western 24 blotting with Bcl-x antibodies specific for each isoform confirmed the RT-PCR results (Figure 4C, lower panel). Therefore, these data demonstrate that E2F1 also controls the alternative
splicing of Bcl-x.

3 Finally, we investigated whether SC35 was involved in these effects. siRNAs targeting 4 sc35 were transfected in H358/Tet-On/E2F1 cells, and expression of *caspases* and *Bcl-x* splice 5 variants was analyzed by RT-PCR. In the absence of E2F1 induction, the knock-down of sc35 6 using two independent siRNAs (Figure 4D and Supplementary Figure 1) did not significantly 7 alter the level of *caspases-8L*, -8a, -9a or -9b mRNAs, nor that of $Bcl-x_L$ or $Bcl-x_S$. Importantly, 8 the induction of E2F1 expression in these cells deprived of SC35 did not affect the splicing 9 pattern of these genes (Figure 4D and Supplementary Figure 1). Furthermore, when we 10 performed RT-PCR analyses in A549 cells transiently transfected with a vector encoding SC35, 11 we found that overexpression of SC35 affected the splicing profile of *caspase-8*, -9 and *Bcl-x* 12 pre-mRNAs in a similar way than did E2F1 (compare Figure 4E to Figures 4B and C) and 13 induced apoptosis (data not shown). Altogether, these results demonstrate that E2F1 requires 14 SC35 to regulate the pre-mRNA alternative splicing of apoptotic genes.

15

E2F1 and SC35 proteins are upregulated and required for apoptosis in response to genotoxic stresses

So far, our results demonstrate the ability of overexpressed E2F1 and SC35 to modify the splicing pattern of various apoptotic genes. Thus, we next attempted to identify in which physiological context both proteins could cooperate to induce apoptosis. It is now well-known that DNA damaging agents stabilize E2F1 and induce its transcriptional activity towards apoptotic genes thereby causing apoptosis ²¹⁻²². In agreement with previous reports, treatment of H358 cells with either methylmethanesulfonate (MMS) or cyclophosphamide, two alkylating

1 agents that create inter-strand DNA crosslinks, significantly increased E2F1 expression as 2 detected by immunoblotting (Figure 5A, upper panel). In these conditions, upregulation of E2F1 3 was accompanied by an increase of SC35 protein and mRNA expression (Figure 5A, upper 4 panels), as well as by the induction of apoptosis (Figure 5A, lower panel). In cyclophosphamide-5 treated cells, the neutralization of E2F1 using siRNAs prevented the accumulation of SC35 6 (Figure 5B), indicating that E2F1 was involved in SC35 induction. In addition, as detected by 7 ChIP experiments, the binding of endogenous E2F1 to the sc35 promoter was increased 8 following drug treatment, indicating that SC35 is a direct target of E2F1 in response to DNA 9 damaging agents (Figure 5C). Furthermore, inhibiting SC35 expression strongly repressed 10 apoptosis following cyclophosphamide treatment, as detected by immunoblotting of pro- or 11 cleaved caspase-3 and Hoechst 33342 staining (Figure 5D). Taken together, these results 12 demonstrate that E2F1 requires SC35 to induce apoptosis in response to genotoxic stresses.

13 Finally, we analyzed whether E2F1 and SC35 acted through regulation of the alternative 14 splicing of apoptotic genes and studied the expression pattern of *caspases -2*, -8 and -9 as well as 15 Bcl-x splice variants by RT-PCR following cyclophosphamide treatment. As shown in Figure 6A 16 (left panel), an increase of pro-apoptotic caspase-9a and Bcl-x_s mRNA levels was observed in 17 cyclophosphamide-treated cells together with a decrease of anti-apoptotic caspase-9b and $Bcl-x_L$ 18 splice variants. Again, immunoblotting experiments confirmed the downregulation and 19 upregulation of Bcl-x_L and Bcl-x_S proteins, respectively (Figure 6A, right panel). In contrast, 20 accumulation of *caspase-2L* and of both anti- and pro-apoptotic *caspase-8L* and *-8a* transcripts 21 was detected in cyclophosphamide-treated cells (Figure 6A, left panel). Therefore, these results 22 demonstrate that cyclophosphamide modifies the alternative splicing pattern of Bcl-x and 23 caspase-9 pre-mRNAs in favor of pro-apoptotic splice variants. Importantly, the neutralization of 24 either e2f1 or sc35 before cyclophosphamide cell treatment prevented these modifications, as detected by RT-PCR (Figure 6B, upper panel) and western blotting (Figure 6B, lower panel).
 Overall, these data strongly suggest that E2F1 and SC35 proteins act together during apoptosis of
 DNA-damaged cells by controlling *Bcl-x* and *caspase-9* pre-mRNAs alternative splicing.

4

5 **Discussion**

6

7 E2F1 is a transcription factor that plays a critical role in cell cycle progression by favoring 8 entry into S phase. Besides its role in cell cycle control, E2F1 is also widely accepted as an 9 inducer of apoptosis. It has been well-demonstrated that E2F1 promotes apoptosis through both 10 transcription-dependent and -independent mechanisms. So far, numerous apoptotic genes whose transcription is enhanced by E2F1 have been identified ¹⁰. In this study, we show that E2F1 11 12 switches the alternative splicing pattern of key apoptotic genes in favor of their pro-apoptotic 13 splice variants, and identify the SC35 protein, a member of the SR family of splicing regulators, 14 as a key direct target of E2F1. Interestingly, two high throughput studies using ChIP on Chip analysis²³ or DNA microarrays²⁴ previously suggested that SC35 is an E2F1-regulated gene. In 15 16 this study, we provide the first evidence of a direct functional link between E2F1 and SC35 17 proteins to regulate cellular apoptosis. Therefore, besides its ability to transactivate pro-apoptotic 18 target genes, E2F1 is also able to control pre-mRNA processing events to induce apoptosis.

19 It has now emerged from the <u>literature</u> that splicing not only depends on the interaction of 20 splicing factors with their target pre-mRNAs, but is also coupled to transcription ²⁵. Indeed, 21 variations of pol II promoter structure can lead to differences in alternative splicing of the 22 transcript ²⁶⁻²⁷ and components of the spliceosome such as the p54nrb (p54 nuclear RNA binding 23 protein) and PSF (polypyrimidine tract-binding protein-associated splicing factor) RNA binding

proteins are involved in both transcription and splicing processes ²⁸ (for review). In addition, 1 2 transcriptional coregulators of the nuclear receptor family recruited at the promoter level not only 3 enhance the transcriptional activity of this promoter, but also affect the nature of the splice variants produced ²⁸⁻²⁹⁻³⁰. Moreover, some transcription factors have been reported to bind to 4 proteins of the spliceosome and/or display dual functions in splicing and transcription ³¹⁻³². 5 6 Taken together, these results indicate a role for proteins controlling transcription in splicing 7 regulation. In this study, we demonstrate that the transcription factor E2F1 transactivates the 8 expression of sc35, a component of the spliceosome and that both proteins regulate pre-mRNA 9 processing events. Altogether, these results strengthen the connection between the transcriptional 10 and splicing machineries. We show that E2F1 alters the splicing pattern of some of its 11 transcriptional targets such as *c-flip* (Figure 3B), *caspases*-8 and -9 (Figures 4B & 4D). As an 12 increased level of *caspases*-8 and -9 transcripts was also detected in this context, it is possible 13 that the transactivating functions of E2F1 cooperate with SC35 accumulation to regulate pre-14 mRNA processing events. Interestingly, the expression of *c-flip* mRNA was apparently not 15 affected by E2F1 in the same conditions (Figure 3A). It was recently shown that the Spi-1/PU.1 16 transcription factor could modify alternative splicing of a transcriptional target gene, without modulation of its mRNA transcription ³². Therefore, another but not exclusive possibility is that 17 18 E2F1 acts as a scaffold protein to drive SC35 to the nascent transcribed RNA of some of its target genes, according to the cell-specific promoter occupation model²⁵. 19

Apoptosis is one of the cellular processes in which alternative splicing plays important regulatory roles ⁵. Several components of the splicing machinery have already been implicated in apoptotic processes. For example, depletion of SF2/ASF ⁸ induces apoptosis. In addition, overexpression of SC35 alters the splicing of *caspase-2* mRNA, in favor of the pro-apoptotic isoform accumulation ⁷. Furthermore, phosphorylation of SR proteins, which is known to control

their sub-cellular localization as well as their activities, has been reported during apoptosis $^{6-33}$. 1 2 However, the upstream signaling molecules that regulate the expression and/or activity of SR 3 proteins during apoptosis, as well as the endogenous targets of SR proteins in this context remain 4 largely unknown. In this study, we provide evidence that E2F1 triggers apoptosis through SC35 5 accumulation and we demonstrate that both proteins cooperate to affect the splicing pattern of 6 caspase-8, caspase-9, flip and bcl-x genes, in favor of pro-apoptotic splice variants. Taken 7 together, our data identify SC35 as a new mediator of E2F1-induced apoptosis and identify some 8 of its endogenous targets in this setting.

9 Alteration of alternative splicing is believed to contribute to the resistance of tumor cells to chemotherapy, notably through overexpression of anti-apoptotic splice variants ³⁴⁻³⁵. However, 10 11 the molecular mechanisms involved in such processes remain largely unknown. Importantly, and 12 consistent with a role of SR proteins during the response to DNA damage, it has been previously shown that SC35 accumulates following γ -irradiation ³⁶. In addition, it was recently reported that 13 14 the expression of SRp55, another member of the SR protein family, is upregulated and required for apoptosis of p53-deficient cells after mitomycin C treatment ³⁷. In this study, we demonstrate 15 16 that SC35 is upregulated by an E2F1-dependent pathway in response to methylmethanesulfonate 17 or cyclophosphamide treatment. Furthermore, we show that the E2F1 and SC35 proteins are 18 required for apoptosis of DNA-damaged cells and control Bcl-x and caspase-9 pre-mRNAs 19 alternative splicing at the expense of anti-apoptotic splice variants. Therefore, our data strongly 20 suggest that E2F1 and SC35 are key-determinants of the cellular response to chemotherapeutic 21 agents.

To conclude, we highlight the first functional connection between the transcription factor E2F1 and a component of the splicing machinery, SC35, in the control of cellular apoptosis. It is well-known that abnormalities in E2F signalling pathways contribute to tumorigenesis ³⁸.

Accordingly, we previously described a differential pattern of E2F1 protein expression in human lung tumors ³⁹. Interestingly, some SR proteins are overexpressed in ovarian cancer ⁴⁰ and SF2/ASF was recently assessed as a proto-oncogene in human tumors ⁴¹. Therefore, it remains to be determined whether alterations of both E2F1 and SC35 proteins could cooperate to promote carcinogenesis.

6

7 Materials and Methods

8

9 Cell lines, treatment, apoptotic assay, plasmids and transfection

10 A549, H358, H1299 and H69 human lung carcinoma cell lines were cultured as previously described ⁴². The H810 large cell neuroendocrine lung carcinoma cell line was 11 12 cultured in 5% CO₂ at 37°C in RPMI-1640 medium supplemented with 5% (v/v) FCS, 0.005 13 mg/ml insulin, 0.01 mg/ml transferrin, 30 nM sodium selenite, 10 nM hydrocortisone, 10 nM β -14 estradiol and 10 mM HEPES. Murine embryonic fibroblasts (MEF) wild-type and E2F1 -/- were 15 cultured in DMEM (GIBCO) supplemented with 10%(v/v) heat-inactivated FCS. The human 16 lung adenocarcinoma H358/Tet-On/E2F1 and Tet-On/E2F1(E132) inducible clones were obtained as previously described ¹¹. Apoptosis was evaluated by scoring the percentage of 17 18 apoptotic cells on 500 cells after Hoechst 33342 staining. Transient transfections were carried out 19 using Fugene 6 (Roche Diagnostic). Plasmids used in transient transfections were pcDNA3, 20 pCMV-E2F-1, pcDNA3-HA-SC35 and pR264-CAT. Recombinant soluble human FLAG-tagged 21 FasL was purchased from Alexis (San Diego, CA, USA). Methanesulfonic acid methyl ester 22 (MMS) and cyclophosphamide monohydrate were all purchased from Sigma (Saint Quentin 23 Fallavier, France).

2 Antibodies

The anti-E2F1 (C-20), anti-SC35 (H-55) and anti-Bcl- x_L (H5) antibodies were purchased from Santa Cruz, the anti-Bcl- x_s (Ab-1) from Oncogene Research, the anti-E2F1 (KH95) and anti-procaspase-3 from Pharmingen, the anti-FLIP (NF6) from Alexis, the anti-actin (20-33) from Sigma, the anti-SC35 (4F-11) from Euromedex and the anti-SRp20 (7B4) and anti-SF2/ASF from Zymed. Cleaved caspase-3 (Asp175) was from Cell Signaling.

8

9 CAT assays

For CAT assay measurements, $2x10^5$ cells per well were seeded in duplicate in 6-well 10 11 plates, and transfected with the pR264CAT plasmid in the presence or absence of increasing amounts of pCMV-E2F1 vector. pR364CAT vector contains the 1kb human sc35 promoter¹² 12 13 and encompasses two putative E2F1 binding sites at -170 (TTTGGCCCG) and -236 14 (TTTCGCGGG) bp upstream of the transcription start site. Transfection was performed using 15 Fugene 6 according to the manufacturer's instructions, and CAT activity was measured 24-48 16 hours after transfection using CAT ELISA (Roche Diagnostic). CAT activity was then 17 normalized in each sample according to the protein amount.

18

19 Chromatin immunoprecipitation experiments

20 Chromatin immunoprecipitation experiments were performed in H358 cells, H1299 cells 21 or H358/Tet-On/E2F1 cells cultured in the presence of 1 μ g/ml doxycylin for 24 hours. An equal 22 amount of chromatin (25 μ g) was precleared and immunoprecipitated with a polyclonal antibody 23 specific for E2F1 (C-20, Santa Cruz) or unrelated rabbit IgG or no antibody, overnight at +4°C.

1 Co-immunoprecipitated chromatin was analyzed for the presence of sc35 promoter DNA 2 between -296 and -79 bp, -upstream of the sc35 transcription start site, -by semiguantitative 3 PCR. This fragment encompasses two putative E2F1 binding sites at -170 and -236 bp upstream 4 transcription start site. The primers used were as follow: forward 5'of the 5 GAGCACCTCCTCTTCCTCCTG-3' and reverse 5'-CCGGAAATGAAACCTTCTGA-3'. PCR 6 conditions were 94°C for 3 min, (94°C 30 sec, 55°C 30 sec, 72°C 30 sec) for 36 cycles, and 72°C 7 for 10 min. For Skp2 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) promoter 8 analysis, the specific primers used were SKP2-95 5'-CTCCCCGCCTACCCCGTGG-3', SKP2-9 5'-CAGACCCGCTAAGCCTAGCAACG-3', forward 5'-+135GAPDH 10 AGCTCAGGCCTCAAGACCTT-3' and GAPDH reverse 5'-AAGAAGATGCGGCTGACTGT-3' as previously described ¹³. PCR conditions were 94°C for 3 min, (94°C 30 sec, 57°C for 11 12 gapdh or 63°C for Skp2 30 sec, 72°C 30 sec) for 36 cycles, and 72°C for 10 min. Signals 13 obtained on ethidium bromide stained gels were quantified using ImageJ software and each ChIP 14 DNA sample was normalized according to the corresponding input DNA sample.

15

16 Transfection of siRNA oligonucleotides

17 The sequences designed to specifically target human *sc35* and *e2f1* RNAs were as follow: 5'-18 sc35(1): 5'-GCGUCUUCGAGAAGUACGGTT-3'; sc35(2): 19 UCGUUCGCUUUCACGACAATT-3'; e2f-1(1): 5'-GUCACGCUAUGAGACCUCATT-3'; 20 e2f1(2): 5'-ACAAGGCCCGAUCGAUGUUTT-3'. The second siRNA targeting sc35 was from 21 Invitrogen (Stealth Select RNAi, SFRS2, Invitrogen). The scrambled siRNA oligonucleotides 22 as all interference follow: used control for RNA experiments were as 5'and 5'-CAAGAAAGGCCAGUCCAAGTT-3'. Cells 23 UCGGCUCUUACGCAUUCAATT-3'

1 were transfected with siRNA oligonucleotides duplex using Oligofectamine reagent according to 2 the manufacturer's instruction (Invitrogen). Doxycyclin ($1 \mu g/ml$) was added or not in the culture 3 medium 4 hours after transfection. The cells were analyzed 48 or 72 hours post-transfection. For 4 experiments with cyclophosphamide, cells were transfected for 48 hours with *mismatch*, sc35 or 5 e2f-1 siRNAs, then cyclophosphamide (50 μ M) was added in the culture medium for 24 6 additional hours.

RT/PCR analyses of alternative splice transcripts

9 Total cellular RNAs were isolated using Trizol reagent (Invitrogen). In all condition, 1 μ g 10 of total RNA was reversed transcribed using oligo(dT) primer and MMLV reverse transcriptase 11 (Invitrogen) according to the manufacturer's protocol. The different primer sequences used in 12 this study as well as the PCR conditions are recapitulated in Table 1. Amplification of a cDNA 13 fragment of G3PDH (Invitrogen) was performed in the same PCR reaction as an internal control. 14 PCR products were run on a 1-2% agarose gel and visualized by ethidium bromide staining.

15

16 **Immunoblotting and immunoprecipitation experiments**

Immunoblotting experiments were performed as previously described ¹¹. 17

18

19 **Acknowledgements:**

20 We thank Patricia Betton, Pascal Perron and Celine Lampreia for technical assistance. We thank 21 Johann Soret (IGM, Montpellier) for the pECE-SC35HA and Alain Sureau (CGM, Gif sur 22 Yvette) for pR264-CAT plasmids. We thank Didier Auboeuf, Martin Dutertre, Saadi Khochbin, 23 Johann Soret and Jamal Tazi for encouraging discussions and critical reading of this manuscript.

14	Title	s and legends to figures
15		
16	Figur	e 1: SC35 is upregulated following E2F1 induction.
17	(A) H	358/Tet-On/E2F1 or H358/Tet-On/E2F1(E132) cells were incubated for indicated times in
18	the pr	resence (+) or absence (-) of 1 μ g/ml doxycyclin (Dox). Mutant E2F1(E132) is unable to
19	bind 1	DNA. Expression of E2F1, SC35, SRp20 and SF2/ASF proteins was studied by western
20	blottir	ng. Actin was used as a loading control. (B) H69 and H810 neuroendocrine lung carcinoma
21	cell li	nes were transfected for 72h with mismatch or e2f1 siRNAs as indicated and subjected to
22	weste	rn blot analyses for the detection of E2F1, SC35, SRp20 and SF2/ASF proteins. Actin was
23	used a	as a loading control. (C) Western blot analyses of E2F1, SC35, SRp20 and SF2 protein

expression in E2F1-deficient (E2F1 -/-) and wild-type control Murine Embryonic Fibroblasts
 (MEFs). Actin was used as a loading control.

3

4 Figure 2: SC35 is a direct transcriptional target of E2F1.

5 (A) RT-PCR analysis of sc35 mRNA. H358/Tet-On/E2F1 or H358/Tet-On/E2F1(E132) cells 6 were incubated for 48 or 72 hours in the presence (+) or absence (-) of $1 \mu g/ml$ doxycyclin (Dox) 7 as indicated. Total RNAs were extracted as described in the material and methods section. 8 Amplified g3pdh was used as an internal control. (B) Chloramphenicol Acetyl Transferase 9 (CAT) experiments were performed in the H1299 cell line co-transfected for 48 hours with 1 µg 10 pR264CAT plasmid, encoding CAT under the control of the sc35 promoter, and increasing 11 amounts of pCMV-E2F1 as indicated. The CAT activity obtained in cells transfected with 12 pR264CAT alone was normalized to 1 and a relative CAT activity was then calculated for each 13 condition. Representative data of at least three independent experiments performed in duplicate 14 are shown. (C) Upper panel: H358/Tet-On/E2F1 cells cultured in the presence of doxycyclin for 15 48h were processed for ChIP analysis using C-20 antibody for E2F1. The coprecipitated 16 chromatin DNA was analyzed by semiquantitative PCR using pair of primers that amplify the 17 human sc35, skp2 or gapdh promoter respectively, as described in the material and methods 18 section. IgG was used as an irrelevant antibody. No Ab means that no antibody was used in this 19 case. Input lane corresponds to PCR reactions containing 1% of total amount of chromatin used 20 in immunoprecipitation reactions. As compared to input amount, 0.13% and 0.3% of chromatin 21 was immunoprecipitated by E2F1 antibody at the sc35 and skp2 promoters respectively. Lower 22 panel: Similar ChIP analyses were performed in H1299 cells in order to detect the binding of 23 endogenous E2F1 to the sc35 promoter. The input control corresponds to 0.7% of the amount of

chromatin used per immunoprecipitation. As compared to input amount, 0.035% of chromatin
 was immunoprecipitated by E2F1 antibody.

3

4 Figure 3: SC35 is required for E2F1-induced apoptosis.

5 H358 Tet-On/E2F1 cells were cultured in the presence (+) or absence (-) of doxycyclin for 72h. 6 (A) H358 Tet-On/E2F1 cells were transfected for 72h either with *mismatch* or *sc35* siRNA. 7 Apoptosis was evaluated using Hoechst staining. Results shown are the mean \pm SD of three 8 independent experiments. (B) H358 Tet-On/E2F1 cells were transfected for 72h with either 9 *mismatch* or *sc35* siRNA and subjected to RT-PCR (left panel) and western blot (right panel) 10 analyses. (C) H358/Tet-On/E2F1 cells were transfected for 48h with either mismatch or sc35 11 siRNA, cultured with (+) or without (-) doxycyclin as indicated, and treated or not with 25 ng/ml 12 FasL for 20 additional hours. Apoptosis was evaluated as in (A).

13

Figure 4: E2F1 and SC35 cooperate to affect the alternative splicing pattern of *caspase-8*, *caspase-9* and *Bcl-x* pre-mRNAs.

16 (A) Alternative splicing patterns of *caspases*-2, -8, -9 and *Bcl-x* primary transcripts. Coding and 17 alternative exons are indicated by and , respectively. The position of primers, the expected 18 sizes (in nucleotides) and the names of the RT-PCR products corresponding to the different 19 mRNA isoforms are indicated. The ability of each transcript to encode pro-apoptotic (+) or anti-20 apoptotic (-) protein isoform is depicted on the right. (B, C) H358/Tet-On/E2F1 or H358/Tet-21 On/E2F1(E132) cells were cultured for 48 hours in the presence (+) or absence (-) of doxycyclin, 22 as indicated. Total RNAs were extracted and subjected to RT-PCR analyses using the specific 23 primers depicted in (A). Representative agarose gels of RT-PCR products corresponding to casp-24 2, casp-8, casp-9 and Bcl-x splice variants are presented. The position of splice variants (in bp) is

1 shown on the right, and the various splicing isoforms are named on the left of each panel. g3pdh 2 was used as an internal control. (C) Lower panel: western blot analysis was performed using 3 specific anti-E2F1, anti-Bcl-x_I and anti-Bcl-x_S antibodies. Actin was used as a loading control. 4 Results are representative of three independent experiments. (D) H358/Tet-On/E2F1 cells 5 cultured in the presence (+) or absence (-) of $1 \mu g/ml$ doxycyclin were transfected for 72 hours 6 with either *mismatch* or *sc35* siRNA and processed as in (B). (E) A549 human lung 7 adenocarcinoma cells were transiently transfected for 48 hours with 10 µg pcDNA3.1/SC35 or 8 control (Mock) vector and processed as in (B). Upper panel: immunoblot demonstrating the accumulation of SC35 in cells transfected with pcDNA3.1/SC35 as compared to mock 9 10 transfected cells. Actin was used as a loading control.

11

Figure 5: E2F1 and SC35 proteins are upregulated in cells undergoing apoptosis in response to DNA damaging agents

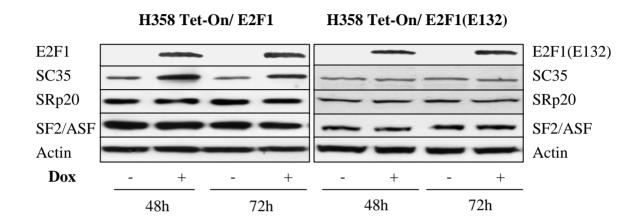

14 (A) H358 cells were treated or not for 24 hours with the indicated cytotoxic agents (50 μ M, each) 15 and analyzed for E2F1 and SC35 protein levels by western blotting (upper panel). sc35 mRNA 16 level was studied by RT-PCR in the same conditions (lower panel). Actin and g3pdh were used 17 as internal controls for immunoblotting and RT-PCR experiments, respectively. Apoptosis was 18 evaluated after Hoechst 33342 staining. Results shown are the mean \pm SD of three independent 19 experiments. (B) H358 cells were transfected for 48 hours with either *mismatch* or *e2f1* siRNA 20 and treated (+) or not (-) for additional 24 hours with cyclophosphamide (50 μ M). Western blot 21 analyses were performed for E2F1 and SC35 detection. (C) Upper panel: H358 cells were treated 22 or not for 24 hours with cyclophosphamide (50 μ M) and ChIP analyses were performed using C-23 20 antibody for E2F1 and primers specific for the human sc35 or gapdh promoter respectively. 24 IgG was used as an irrelevant antibody. No Ab means that no antibody was used in this case. The 1 input reaction represents 0.5% of the total chromatin immunoprecipitated for each sample. As 2 compared to input amount, 0.04% and 0.12% of chromatin was immunoprecipitated by E2F1 3 antibody at the *sc35* promoter level in untreated and treated cells respectively. *Lower panel*: 4 Bands obtained with E2F1 ChIP DNA samples were quantified and normalized relative to the 5 corresponding input DNA sample. Sc35 promoter occupancy in non-treated cells was arbitrarily 6 set at 1. (D) H358 cells were transfected for 48 hours with either *mismatch* or *sc35* siRNA and 7 treated (+) or not (-) for 24 additional hours with cyclophosphamide (50µM). Apoptosis was 8 evaluated after Hoechst 33342 staining and immunoblotting with anti-caspase-3 or cleaved 9 caspase-3 antibody. Results are the mean \pm SD of three independent experiments.

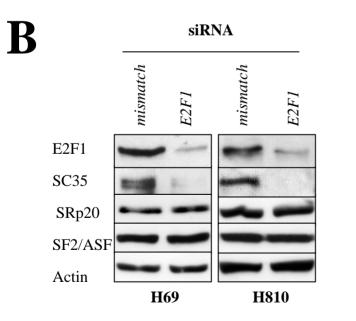

10

Figure 6: E2F1 and SC35 regulate the alternative splicing pattern of *Bcl-x* and *caspase-9* pre-mRNAs in response to cyclophosphamide treatment.

13 (A) H358 cells were treated (+) or not (-) for 24 hours with cyclophosphamide (50 μ M). Left 14 panel: RT-PCR analysis for detection of caspases -2, -8, -9 and Bcl-x splice variants was 15 performed as previously described in Figures 4B and 4C. Right panel: western blot analysis was 16 performed using specific anti-SC35, anti-Bcl-x_L and anti-Bcl-x_S antibodies. Actin was used as a 17 loading control. (B) H358 cells were transfected for 48 hours with either mismatch or e2f1 or sc35 siRNA and treated (+) or not (-) for 24 additional hours with cyclophosphamide (50 µM). 18 19 RT-PCR (upper panel) and western blot (lower panel) analyses of Bcl-x or caspase-9 splice 20 variants were performed as previously described. g3pdh and actin were used as internal controls 21 for RT-PCR and immunoblotting experiments, respectively.
