15

16 Running title : Key role of epithelial GM-CSF for mucosal adjuvant

17

18 **ABSTRACT**

19 The Toll-like receptor 5 (TLR5) agonist flagellin is a potent adjuvant and is currently being  
20 developed for use in vaccines. The mechanisms that drive flagellin's activity are influenced by its  
21 administration route. Previous studies showed that lung structural cells (especially epithelial cells  
22 lining the conducting airways) are pivotal for the efficacy of intranasally administered flagellin-  
23 containing vaccines. Here, we looked at how the airway epithelial cells regulate the flagellin-  
24 dependent stimulation of antigen-specific CD4<sup>+</sup> T cells and the antibody response in mice. Our  
25 results demonstrate that after sensing flagellin, airway epithelial cells trigger the release of  
26 granulocyte-macrophage colony-stimulating factor (GM-CSF) in a TLR5-dependent fashion and  
27 the doubling of the number of activated type 2 conventional dendritic cells (cDC2s) in draining  
28 lymph nodes. Furthermore, the neutralization of GM-CSF reduced cDC2s activation. This resulted  
29 in lower of antigen-specific CD4<sup>+</sup> T cell count and antibody titers in mice. Our data indicate that  
30 during pulmonary immunization, the GM-CSF released by airway epithelial cells orchestrates the  
31 cross-talk between cDC2s and CD4<sup>+</sup> T cells and thus drives flagellin's adjuvant effect.

32

33 **SINGLE-SENTENCE KEY POINTS**

- 34 • Flagellin induces GM-CSF production by airway epithelial cells
- 35 • GM-CSF transactivates lung conventional dendritic cells
- 36 • GM-CSF drives the mucosal adjuvant activity of flagellin/TLR5 signaling

37

## 38 INTRODUCTION

39 Vaccines against infectious diseases is based on the administration of protective, immunodominant  
40 antigens that trigger antibody and T cell responses and thus result in the neutralization or death of  
41 the pathogenic microorganisms. Most antigens are formulated in a way that enables a rapid,  
42 intense, and long-lasting protective response. To optimize immunization, adjuvants can be  
43 included to vaccines in order to promote targeting and stimulation of the innate immune system –  
44 both of which are essential for an appropriate vaccine response (1).

45 Toll-like receptor (TLR) agonists trigger innate immune responses and are used as adjuvant of  
46 vaccination. There are many evidences that TLR signaling enhances vaccine efficacy by  
47 effectively priming the adaptive immune system (2-5). In the context of vaccination, the cells that  
48 respond primarily to TLR agonists include professional antigen-presenting cells (APCs) such as  
49 dendritic cells (DCs), B lymphocytes or macrophages. However, many structural cells including  
50 epithelial cells ubiquitously express pattern recognition receptors (PRRs) - including TLRs – and  
51 therefore respond to TLR agonists (6-11) . There is a large body of literature data on how  
52 monophosphoryl lipid A (an attenuated lipopolysaccharide derivative used in adjuvant  
53 formulation) influences structural and myeloid cells at the site of vaccine injection (2, 12-14).  
54 Indeed, monophosphoryl lipid A triggers TLR4 signaling in the structural cells, which in turn  
55 contributes to the vaccine’s efficacy.

56 Bacterial flagellin is a TLR5 agonist and acts as a potent systemic and mucosal adjuvant (15).

57 Although DCs are essential for flagellin’s adjuvanticity, the process that drives DC activation is  
58 strongly influenced by the immunization route. The adjuvant activity is driven either by the direct  
59 or indirect activation of APCs (especially DCs) (16-22). For example, the long-term, T-cell-  
60 dependent antibody response against systemically administered flagellin from *Salmonella* (FluC)

61 depends on TLR5 signaling in CD11b<sup>+</sup>CD103<sup>+</sup> double-positive conventional DCs (cDCs) (21-23).  
62 In contrast, the delivery of flagellin to the mucosae (especially the airways) potentiates first-line  
63 adaptive responses by structural cells (especially airway epithelial cells, AECs) (24-28). Thus,  
64 intranasal or intratracheal administration of flagellin induces immediate and transient TLR5  
65 signaling in lungs (16, 25, 26, 29, 30). Notably, experiments bone-marrow chimera and  
66 microdissection of lung tissue showed that flagellin activates the structural epithelial airway cells  
67 but does not impact on the alveolar macrophages. TLR5-mediated activation of AECs, in turn  
68 activates lung DCs (16, 27, 28, 31) However, the underlying mechanism remains poorly  
69 understood. Airway epithelial cells respond to flagellin by releasing a broad range of cytokines  
70 and chemokines (such as CCL20, IL-1 $\alpha$ , or IL-1 $\beta$ ) that may impact lung DC maturation. It has  
71 been suggested that the AEC-derived cytokines IL-25, IL-33 and thymic stromal lymphopietin  
72 (TSLP) promote DC activation (27, 28). Furthermore, AEC stimulation by flagellin enhances the  
73 influx of neutrophils and monocytes that may contribute as APCs. Recently, we showed that  
74 neither the IL-1 cytokine family nor neutrophils nor monocytes orchestrate flagellin's mucosal  
75 adjuvant activity (16). In experiments in the mouse (and in contrast to cholera toxin subunit B, a  
76 potent mucosal adjuvant), intranasally administered recombinant flagellin did not enter into the  
77 lung parenchyma and thus could not activate the DCs located there (16, 26). We therefore sought  
78 to establish how cross-talk between AECs and lung cDCs promotes flagellin's mucosal adjuvant  
79 effect. To this end, we used an *in vitro* model based on (i) murine AECs grown at the air-liquid  
80 interface (ALI), and (ii) FMS-like tyrosine kinase 3 Ligand (FLT3L)-derived cDCs from murine  
81 bone marrow. We demonstrated that flagellin-stimulated AECs release GM-CSF in a TLR5-  
82 dependent manner and thus enhance the frequency of activated type 2 CD11b<sup>+</sup> DCs (cDC2s).  
83 Furthermore, activated cDCs loaded with an MHCII-restricted ovalbumin (OVA) peptide primed

84 OVA-specific CD4<sup>+</sup> T cell (OTII cells) and prompted rapid proliferation of the latter. Disruption  
85 of GM-CSF signaling abrogated the flagellin- and AEC-dependent activation of cDCs and the  
86 subsequent activation of OTII cells. We next tested the effect of flagellin-induced GM-CSF on  
87 lung cDCs *in vivo*. Epithelium-derived GM-CSF significantly increased the frequency of cDC2s  
88 in the lung-draining mediastinal lymph nodes (MdLNs). In mice, the antibody-based blockade of  
89 GM-CSF signaling reduced the number of activated cDC2 in the MdLNs. In turn, this drastically  
90 reduced titers of antigen-specific CD4<sup>+</sup> T-cell-dependent IgG antibodies. Taken as a whole, our  
91 results suggest that AEC-derived GM-CSF initiates the cross-talk between lung CD11b<sup>+</sup> cDCs and  
92 antigen-specific T cells, and thus promotes the mucosal adjuvant effect of flagellin.

93

94 **MATERIALS AND METHODS**

95 **Ethics statement.** Animals were maintained in a pathogen-free facility in compliance with  
96 institutional guidelines at the Institut Pasteur de Lille (animal facility agreement #C59-350009).  
97 All experiments complied with current national, institutional and European regulations and ethical  
98 guidelines, were approved by our Institutional Animal Care and Use Committee (reference:  
99 APAFIS#5164, protocol 2015121722429127\_v4) and were conducted by qualified, accredited  
100 personnel.

101 **Animals**

102 Six- to eight-week-old female C57BL/6JRj mice (Janvier Labs, Saint Berthevin, France), OT-II,  
103 *Tlr4*<sup>-/-</sup> and *Tlr5*<sup>-/-</sup> mice (backcrossed on C57BL/6J) were used.

104 **Reagents**

105 The custom-designed flagellin primarily used in the present study (recombinant flagellin FliC<sub>Δ174-</sub>  
106 <sub>400</sub> harboring a carboxy-terminal histidine Tag) derives from *Salmonella enterica* serovar  
107 Typhimurium FliC (32, 33). The recombinant FliC<sub>Δ174-400/89-96\*</sub> (referred to henceforth as  
108 FliC<sub>TLR5mut</sub>, and which does not signal through TLR5) was generated by replacing the residues  
109 involved in TLR5 detection (89-96, QRVRELAV) with the corresponding sequence from a non-  
110 signaling flagellin (DTVKVKAT) (29, 32, 33). The recombinant flagellins were expressed in  
111 inclusion bodies in *Escherichia coli* BL21(DE3) and then purified to homogeneity with metal  
112 affinity, ion-exchange, gel filtration and fast protein liquid chromatography techniques (GE  
113 Healthcare, Pittsburgh, PA) after endotoxin depletion. Using a *Limulus* assay (Pierce LAL  
114 Chromogenic Endotoxin Quantitation Kit, Thermo Fisher Scientific, Waltham, MA), we estimated  
115 the final endotoxin content in the protein preparation to be 0.016 endotoxin units per μg of protein.  
116 The molecular consistency and biological activity of FliC<sub>Δ174-400</sub> and FliC<sub>TLR5mut</sub> were quality-

117 controlled as described in **Supplementary Figure 1 A-C**. Endograde OVA (Hyglos, Bernried,  
118 Germany) and OVA-specific MHCII-restricted peptide (Invivogen, San Diego, CA) were used in  
119 the present study. The anti-GM-CSF antibody (clone MP1-2EE9) and the isotype control (clone  
120 2A3) were obtained from BioXcell, West Lebanon, NH. Recombinant murine FMS-like tyrosine  
121 kinase 3 ligand (FLT3L) was purchased from Peprotech, Neuilly-Sur-Seine, France.

### 122 **Immunization and sample collection**

123 Mice were lightly anesthetized (using gaseous isoflurane) prior to intranasal  
124 immunization/treatment in a maximum volume of 30  $\mu$ l. Unless otherwise specified, a homologous  
125 prime-boost immunization protocol was used to assess the specific adaptive immune responses to  
126 OVA (10  $\mu$ g) as the model antigen and the flagellin FliC $_{\Delta 174-400}$  (2  $\mu$ g) as the adjuvant. For cDC  
127 activation and time-course studies, mice were sacrificed at 6 hours and 18 hours following  
128 intranasal instillation of FliC (2  $\mu$ g). For GM-CSF depletion studies, animals were treated with  
129 60  $\mu$ g of GM-CSF-specific antibody or isotype control 2 hours prior to immunization, with an  
130 additional 60  $\mu$ g of antibody then administered intranasally at the same time as the flagellin and/or  
131 OVA. Bronchoalveolar lavage (BAL), MdLNs, lung, spleen and serum samples were collected as  
132 described previously (16, 26, 32). Lung extract were prepared by homogenizing the lung in 2 ml  
133 of Tissue Protein Extraction Reagent (Pierce, Rockford, IL).

### 134 **Antigen-specific immune responses.**

135 Titers of OVA-specific antibodies in serum and BAL samples were assessed using an ELISA. The  
136 ELISA plates were prepared by absorption of OVA (1  $\mu$ g/ml in phosphate-buffered saline (PBS))  
137 or anti-mouse IgG (5  $\mu$ g/ml in PBS; product 1031-01 from SouthernBiotech, Birmingham, AL)  
138 overnight at 4 °C on Maxisorp microplates (Nunc, Rochester, NY), and blocking for 1 h at room  
139 temperature with 1% dried milk in PBS. Next, the ELISA plates were incubated for 1 h at room

140 temperature with serial dilutions (for coated plates) of the serum samples or (for anti-mouse IgG-  
141 coated plates) of IgG standards (IgG, I5381, Sigma-Aldrich, Saint Louis, MO). Primary antibody  
142 binding was revealed by subsequent incubations with a biotin-conjugated goat anti-mouse IgG  
143 antibody (SouthernBiotech), a peroxidase-streptavidin complex (RPN1231, GE Healthcare,  
144 Chicago, IL), and tetramethylbenzidine (555214, BD Biosciences, Franklin lakes, NJ), and  
145 measured using a microplate reader at wavelengths of 450 and 570 nm. Absolute quantities of  
146 antibodies were calculated according to standard curves and expressed in ng/ml.

147 **Cytokine production.** Cytokine levels in serum, BAL, lung extract or cell culture supernatants  
148 were measured using commercial ELISA kits for GM-CSF, IL-2, CCL20 (all from R&D Systems,  
149 Minneapolis, MN) and IFN $\gamma$  (Invitrogen, Carlsbad, CA).

#### 150 **Air-liquid interface (ALI) cultures of AECs, and the production of conditioned medium**

151 Mouse AEC cultures were established as described previously (34, 35). The AECs were isolated  
152 by overnight incubation of mouse trachea with 0.15% pronase (Roche) at 4°C. The cells were  
153 seeded on collagen-coated Transwell<sup>®</sup> inserts (Corning<sup>™</sup>, Corning, NY; one insert per mouse).  
154 The ALI cultures were established once the cells' transepithelial resistance exceeded 1000  $\Omega\text{cm}^2$   
155 (usually within one week). The medium was then removed from the apical side. The AECs were  
156 treated by adding 10  $\mu\text{l}$  of 1  $\mu\text{g}/\text{ml}$  of flagellin FliC $_{\Delta 174-400}$  or PBS alone (control) to the apical side  
157 of the insert. The conditioned medium was collected from the basal compartment after 24 h,  
158 aliquoted, and stored at -80°C prior to the cytokine assay or to treatment of DCs.

#### 159 **Production of FLT3L-derived bone marrow DCs**

160 Conventional DCs were derived from the bone marrow (BM) of animals, as described previously  
161 (36, 37). Briefly, BM cells were isolated from mice, and any red blood cells were lysed. Next, 10<sup>7</sup>  
162 cells were suspended in 5 ml of RPMI complete medium supplemented with 100 ng/ml of mouse

163 recombinant FLT3L (Peprotech). The cells were seeded into a single well of a 6-well plate (Ultra-  
164 low binding, Corning™). After 3 days of culture, the cell suspension was divided into two  
165 volumes, and 2.5 ml of fresh medium supplemented with 100 ng/ml of recombinant FLT3L was  
166 added to each. The process was repeated on day 6, and the cells were ready to use on day 9.

### 167 **Flow cytometry**

168 Cell suspensions of lung, MdLNs or spleen were obtained by enzymatic digestion with collagenase  
169 from *Clostridium* type IA (1 mg/mL, Sigma-Aldrich) and DNase I (40 µg/ml, Sigma-Aldrich) for  
170 30 min at 37°C. For lungs, hematopoietic cells were recovered after centrifugation on Percoll 20%  
171 (GE Healthcare), incubated with anti-CD16/CD32 FcR blocking antibodies (clone 2.4G2), and  
172 then stained with specific antibodies. The following antibodies were used to study tissue cells and  
173 BMDC populations: anti-Gr1-FITC (clone RB6-8C5, BioLegend, San Diego, CA), anti-CD3ε-  
174 FITC (clone 145-2C11, BD Biosciences), anti-B220-FITC (clone RA3-6B2; BioLegend), anti-  
175 CD64-PE (clone X54-5/7.1; BioLegend), anti-SiglecF-AF647 (clone E50-2440; BD Biosciences),  
176 anti-CD11b-BV786 (clone M1/70; BioLegend), anti-MHC II-PB (clone M5/114.15.2;  
177 BioLegend), anti-CD11c-PE/Cy7 (clone N418; BioLegend), anti-CD24-PerCP-Cy5.5 (clone  
178 M1/69; BioLegend), anti-CD45-APC-Cy7 (clone 30F11; BioLegend), anti-CD86-BV605 (clone  
179 GL1; BioLegend), anti-CD80-PE/Cy5 (clone 16-10A1; BioLegend). To study vaccine-induced  
180 OVA-specific T cells: anti-CD3ε -FITC, anti-CD4-APC/Fire750 (clone RM4-5; BioLegend), anti-  
181 CD8-PeCy7 (clone 53-6.7; BioLegend), anti-CD45-BV650 (clone 30F11; BioLegend) and  
182 CellTrace™ Violet (CTV; Invitrogen) were used. Dead cells were excluded from the analysis by  
183 using Live/Dead Aqua dye (Invitrogen). Cells were stained with surface-specific antibodies for  
184 30 min at 4°C. Data were collected on a BD LSR Fortessa (BD Biosciences) and analyzed with  
185 FlowJo software (V10).

186 **Gene expression analysis**

187 Total RNA from AECs was isolated with a Nucleospin RNA kit (Macherey-Nagel). The RNA was  
188 reverse-transcribed with a High-Capacity cDNA Archive Kit (Applied Biosystems), according to  
189 manufacturer's instructions. Gene expression was quantified by cDNA amplification in a  
190 QuantStudio 12K real-time PCR system (Applied Biosystems, Foster City, CA), using Power  
191 SYBR® Green PCR Master Mix (Applied Biosystems). Relative mRNA levels ( $2^{-\Delta\Delta Ct}$ ) were  
192 determined by comparing (i) the cycle thresholds (Ct) for the gene of interest and for *Actb* ( $\Delta Ct$ )  
193 and (ii) the  $\Delta Ct$  values for treated and control groups ( $\Delta\Delta Ct$ ). The upper boundary for Ct was set  
194 to 35 cycles.

195 **Co-cultures of CD4 lymphocytes and DCs.**

196 CD4 cells were isolated from the lymph nodes and spleen of OTII mice, using negative selection  
197 (CD4 isolation kit, Miltenyi Biotec, Bergisch Gladbach, Germany). The cells were next stained  
198 with CTV, according to manufacturer's instructions. The conditioned media from flagellin- or  
199 PBS-treated AECs were incubated with 10  $\mu\text{g/ml}$  of anti-GM-CSF or isotype antibody for  
200 30 minutes at 37°C. FLT3L-derived BMDCs were treated with the antibody-pre-incubated, AEC-  
201 conditioned media for 18 hours. After washing with RPMI medium, the DCs were loaded with  
202 2  $\mu\text{g/ml}$  of MHCII-restricted, OVA-specific peptide (OVA<sub>323-339</sub>; Invivogen). Following a 4-hour  
203 incubation at 37°C, the DCs were washed and then incubated with CTV-stained CD4 T cells at a  
204 ratio of 1:20 for 4 days. The proliferation of OT-II cells was assessed using flow cytometry.

205 **Statistics**

206 Statistical analysis was performed using GraphPad Prism version 8 software (San Diego, CA).  
207 Groups were compared using a Mann-Whitney test (for two independent groups) or Kruskal-

208 Wallis one-way ANOVA with Dunn's post-test (for three or more groups). Unless otherwise  
209 specified, the results were expressed as the mean  $\pm$  standard error of the mean (SEM).

210

211

## 212 **RESULTS**

### 213 *Flagellin's activity as a mucosal adjuvant is dependent on TLR5 signaling and CD4<sup>+</sup>T cells*

214 To confirm the involvement of TLR5 signaling in flagellin's mucosal adjuvant activity, mice were  
215 immunized intranasally on days 0 and 21 with ovalbumin alone or formulated with FliC<sub>Δ174-400</sub> or  
216 FliC<sub>TLR5mut</sub> (i.e. the counterpart with a defect in TLR5 signaling). We found that mice immunized  
217 with OVA and FliC<sub>TLR5mut</sub> had very low serum OVA-specific antibody titers similar to mice  
218 immunized with OVA only (**Figure 1A**). In contrast, a combined formulation of OVA and  
219 FliC<sub>Δ174-400</sub> was associated with 100-fold more elevated titers of serum OVA-specific antibodies.  
220 The specific *ex vivo* stimulation of lung-draining MdLN cells with OVA enhanced CD4<sup>+</sup> T cell but  
221 not CD8<sup>+</sup> T proliferation solely in animals that had received FliC<sub>Δ174-400</sub> and OVA (**Figure 1B**).  
222 Concordantly, OVA-stimulated MdLN cells secreted high levels of IFN $\gamma$  and IL-2 when animals  
223 were immunized with FliC<sub>Δ174-400</sub> (**Supplementary Figure 1D**). However, this effect of  
224 immunization was not observed with cells isolated from spleen or lungs since no cytokines were  
225 detectable in supernatant of OVA-stimulated cells. Since the elevation in the antigen-specific  
226 CD4<sup>+</sup> T cell count was correlated with the serum antibody titer, we further evaluated the  
227 contribution of CD4<sup>+</sup> T cells to flagellin's mucosal adjuvant activity. Antibody-based depletion of  
228 CD4<sup>+</sup> T lymphocytes prior to immunization drastically reduced the levels of OVA-specific  
229 antibodies (**Figure 1C**). Taken as a whole, these results demonstrated that FliC<sub>Δ174-400</sub>'s mucosal  
230 adjuvant activity is TLR5-dependent and requires antigen-specific CD4<sup>+</sup> T cells.

231

### 232 *Airway epithelial cells sense flagellin via TLR5 to release GM-CSF*

233 We and others have found that AECs are the primary targets for flagellin's mucosal activity (24-  
234 28). The AECs that make up a large proportion of lung structural cells release chemokines and  
235 cytokines, which in turn can recruit DCs, modulate the cells' functions, and shape a potent immune  
236 response. We therefore sought to investigate the DC-modulating cytokines that are released by  
237 AECs in response to flagellin. To this end, we studied cultures of tracheal epithelial cells from *in*  
238 *vitro* ALI cultures. The cells differentiated into a complex set of AECs that recapitulated the cell  
239 composition and structures found in the bronchial epithelium. We found that administration of  
240 flagellin FliC $\Delta$ 174-400 at the air interface stimulated the expression of several genes linked to innate  
241 immune signaling (**Figure 2A**). We observed that the mRNA expression of the *Csf2* gene (coding  
242 for GM-CSF) was significantly upregulated (~10 fold) 2 hours after flagellin treatment, whereas  
243 the genes for other DC-modulating cytokines (such as TSLP, IL-33 and IL-25) were not affected.  
244 Moreover, the polarized secretion of GM-CSF into the basal compartment of flagellin-stimulated  
245 AECs was enhanced after 24 hours (**Figure 2B**). Next, we probed the contribution of TLR5  
246 signaling on AECs to the production of GM-CSF, using AECs from *Tlr5*<sup>-/-</sup> mice. We found that  
247 *Tlr5*<sup>-/-</sup> AECs did not secrete any GM-CSF when stimulated with FliC $\Delta$ 174-400 (**Figure 2C**).  
248 Similarly, we demonstrated that freshly isolated alveolar epithelial cells  
249 (CD45<sup>neg</sup>CD31<sup>neg</sup>Ter119<sup>neg</sup>Epcam<sup>+</sup>) from naïve animals were stimulated by flagellin to upregulate  
250 *Csf2* mRNA levels, whereas this did not occur in cells from *Tlr5*<sup>-/-</sup> animals  
251 (**Supplementary Figure 2A-B**). Using intranasal flagellin instillation, we next investigated  
252 whether GM-CSF could be detected in the respiratory compartments. In agreement with our *in*  
253 *vitro* observations, GM-CSF was detected in the BAL (**Figure 2D**) of animals - most prominently  
254 4 hours after the treatment. Interestingly, GM-CSF production was upregulated in mouse BAL  
255 after the administration of the native form flagellin FliC, whereas TSLP, IL-33 and IL-25 were

256 barely detected (**Supplementary Figure 2C-D**). These data suggest that AECs detect flagellin and  
257 promote the secretion of GM-CSF in a TLR5-dependent manner.

258

### 259 *Type 2 cDCs respond to GM-CSF released by flagellin-stimulated AECs*

260 Since lung-resident cDC2 are required for flagellin's adjuvant effect, we next looked at how AECs  
261 interact with cDC2. To this end, total mouse BM cells were differentiated into cDCs using the  
262 growth factor FLT3L. The resulting cells closely resembled the DC population found in murine  
263 tissues, including cDC1s, cDC2s, and plasmacytoid DCs. To circumvent any direct activation of  
264 DCs by flagellin, we generated FLT3L-derived cDCs from *Tlr5*<sup>-/-</sup> mice. The conditioned medium  
265 collected from the basal compartment of the flagellin FliC<sub>Δ174-400</sub>-treated AECs was incubated with  
266 FLT3L-derived cDCs and compared with mock-conditioned AEC medium (**Figure 3A**). Our  
267 initial experiments demonstrated that flagellin-conditioned medium was able to influence DCs.  
268 This stimulation was characterized by an enhanced number of activated cDC2s, as demonstrated  
269 by the increased frequency of the CD80<sup>+</sup>CD86<sup>+</sup>-expressing CD11b<sup>+</sup>CD24<sup>dim</sup> cDC2 population.  
270 Since GM-CSF production was identified as being differentially regulated by FliC<sub>Δ174-400</sub>, we  
271 addressed the factor's contribution to DC maturation by neutralizing it with a specific monoclonal  
272 antibody (**Figure 3B-C**). The neutralization of GM-CSF in flagellin-conditioned medium was  
273 associated with a significantly lower mean  $\pm$  SD frequency of activated cDC2s (46.5 $\pm$ 4.95%),  
274 relative to the control group of isotype-treated cells (72.4 $\pm$ 6.26%). Moreover, the expression of  
275 the activation markers CD80 and CD86 was significantly higher when for cells exposed to  
276 flagellin-conditioned AEC medium and the isotype antibody, compared with mock-conditioned  
277 controls. This effect was completely blocked by GM-CSF-specific antibodies (**Figure 3C**). Taken

278 as a whole, these data demonstrated that the GM-CSF produced by flagellin-stimulated AECs is  
279 essential for regulating the number and activation status of FLT3L-derived cDC2s.

280

### 281 ***GM-CSF improves the ability of cDCs to prime antigen-specific CD4<sup>+</sup> T cells***

282 To determine the contribution of GM-CSF-exposed cDC to the priming of CD4<sup>+</sup> T cells, we carried  
283 out an *in vitro* experiment with conditioned-medium-treated, OVA-specific MHCII peptide-  
284 loaded-DCs and CD4<sup>+</sup> T lymphocytes from OTII mice (**Figure 4A**). Briefly, FLT3L-derived DCs  
285 that had been exposed to AEC-conditioned medium and antibodies were loaded with MHCII-  
286 restricted OVA<sub>323-339</sub> peptide prior to incubation with CTV-labeled OVA-specific CD4<sup>+</sup> T cells  
287 from OT-II mice. By measuring the dilution of CTV, we evaluated the proportion of CD4<sup>+</sup> T cells  
288 that had divided after exposure to antigen and DCs (**Figure 4B**). Mock-conditioned medium  
289 promoted the division of about 18.9% of the CD4<sup>+</sup> T cells, whereas flagellin-conditioned medium  
290 significantly promoted the division of proliferating CD4<sup>+</sup> T cells (25%) (**Figure 4B-C**). The  
291 neutralization of GM-CSF during the incubation of DCs with flagellin-conditioned medium  
292 strongly impaired T cell proliferation (**Figure 4C**). Remarkably, antibody treatment yielded  
293 proliferation levels similar to those obtained with mock-conditioned medium.

294 Given the influence of the DC-T cell interaction on T cell priming, we sorted cDC2s from the  
295 MdLN of mice that had been immunized with flagellin and OVA in the presence of a GM-CSF-  
296 specific antibody prior to incubation with CTV-stained OTII cells (**Supplementary Figure 3A-**  
297 **C**). Strikingly, cDC2s from anti-GM-CSF-treated mice were less efficient in priming the CD4<sup>+</sup> T  
298 cells than cDC2s from mock mice. Therefore, our data suggest that the secretion of GM-CSF by  
299 flagellin-stimulated AECs orchestrates CD4<sup>+</sup> T cell activation by promoting the functional  
300 maturation of cDC2s.

301

302 ***Flagellin-dependent GM-CSF production in the lung enhances the number of cDC2s in MdLNs***

303 After being activated, lung cDCs migrate to the MdLNs, where they prime T cells and help to  
304 mount an effective adaptive response (16, 26, 31). To validate our *in vitro* observations, we  
305 determined whether or not flagellin-mediated GM-CSF production in the lung drive the increase  
306 in the frequencies and activation status of MdLN DCs (**Figure 5A**). Using fluorescently labelled  
307 OVA (OVA<sub>AF647</sub>), we found that cDC2s are the predominant OVA-carrying DCs in the MdLNs  
308 when this protein is given intranasally at the same time as flagellin (**Supplementary Figure 3D**).  
309 Intranasal instillation of flagellin increased the cDC2s (as a proportion of total DCs), compared  
310 with naïve animals (62% vs. 46%). In contrast, the proportion of cDC1s did not change  
311 (**Figure 5B**). Concomitantly, we observed a significantly lower proportion (51%) of cDC2s in  
312 animals that had received anti-GM-CSF antibody along with flagellin, relative to isotype-treated  
313 animals) (**Figure 5C**). Furthermore, one third of the animals that received anti-GM-CSF antibody  
314 had almost the same cDC2 levels as in naïve mice. Furthermore, the frequency of  
315 CD80<sup>+</sup>CD86<sup>+</sup> cDC2 was significantly lower in experiments with neutralized GM-CSF  
316 (**Figure 5D**). Lastly, the cDC2s were less activated, as evidenced by the significantly lower median  
317 fluorescence intensity for CD80 following GM-CSF-specific antibody treatment but not following  
318 treatment with an isotype control (**Figure 5E**). Taken as a whole, these data show that flagellin-  
319 driven GM-CSF production in the lung significantly upregulates the proportion of activated cDC2s  
320 in lung-draining MdLNs.

321

322 ***In vivo neutralization of GM-CSF abrogates the mucosal adjuvant activity of flagellin***

323 To demonstrate that modulating the function and number of cDCs in the MdLN can affect  
324 flagellin's mucosal adjuvant activity, we performed prime-boost immunization with flagellin and  
325 OVA antigen at the same time as the treatment with an anti-GM-CSF antibody or an isotype control  
326 (**Figure 6A**). After ex vivo stimulation with OVA, 1.53% of the MdLN CD4<sup>+</sup> T cells isolated  
327 from animals immunized with flagellin and OVA and then treated with an isotype antibody were  
328 found to be dividing (**Figure 6B**). In contrast, the proportion of dividing CD4<sup>+</sup> T cells in animals  
329 that received anti-GM-CSF was only 0.44%; this corresponded to a 3-fold relative reduction. To  
330 check whether the number of antigen-specific CD4<sup>+</sup> T cells was correlated with the titer of antigen-  
331 specific antibodies, OVA-specific antibodies were assayed in the serum and BAL of immunized  
332 animals. Both titers were significantly lower in mice that received anti-GM-CSF antibody than  
333 isotype-treated mice (**Figure 6C**). Furthermore, we did not observe any correlation between the  
334 frequency of cDC1s and the titer of OVA-specific antibodies following GM-CSF neutralization  
335 ( $R^2=0.21$ ,  $p=0.0852$ ) (**Supplementary Figure 3E**). However, we observed a strong, positive  
336 correlation between the frequency of cDC2s and the titer of OVA antibodies ( $R^2=0.72$ ,  $p<0.0001$ ).  
337 This correlation suggested that flagellin-dependent GM-CSF production in the lung is important  
338 for mediating flagellin's adjuvant activity via cDC2 activation.  
339

340 **DISCUSSION**

341 Airway epithelial cells are known to secrete factors that can influence a wide range of immune  
342 cells in the lung (6). The AECs' ability to drive immunological changes during allergen exposure  
343 has been well characterized. Our present data reveal a new role for AECs: promoting the mucosal  
344 adjuvant activity of flagellin by the local production of GM-CSF and transactivation of lung DCs.  
345 Our *in vitro* ALI cultures of AECs and DCs provided a comprehensive view of how GM-CSF  
346 released from flagellin-stimulated AECs orchestrates the cross-talk between cDC2s and antigen-  
347 specific CD4<sup>+</sup> T cells. This is consistent with *in vivo* data suggesting that GM-CSF recruits cDC2s  
348 into lung-draining lymph nodes and thus helps to prime antigen-specific CD4<sup>+</sup> T cells. These  
349 results underline the importance of GM-CSF production by AECs in flagellin's adjuvant activity.  
350 GM-CSF is a pleiotropic cytokine expressed by both hematopoietic and non-hematopoietic cells,  
351 and is known to regulate the proliferation and differentiation of various hematopoietic cells,  
352 including DCs (38). The release of GM-CSF by AECs and the critical role of the GM-CSF receptor  
353 in the development of DCs in nonlymphoid tissue suggest the existence of cross-talk between  
354 structural cells and hematopoietic cells (39-43). The expression of *Csf2* in flagellin-stimulated  
355 alveolar epithelial cells and in ALI AEC cultures was upregulated (**Figure 2 and Supplementary**  
356 **Figure 2**). This finding was further corroborated by the low levels of GM-CSF expression in  
357 flagellin-treated *Tlr5*<sup>-/-</sup> AECs, and also fits with our previous report in which the flagellin-driven  
358 expression of *Csf2* in murine lungs was restricted to radioresistant structural cells (26). These  
359 results are in agreement with observations in which nasal epithelial cells upregulate the production  
360 of GM-CSF (43). Further investigations using conditional knockout models where the *Tlr5* and  
361 *Csf2* genes are inactivated in the airway epithelial cell compartments will be instrumental to

362 demonstrate unambiguously that the flagellin-mediated adjuvant activity is dependent on GM-CSF  
363 released by AECs.

364 Recent research has suggested that DC influence flagellin's mucosal activity when the adjuvant is  
365 delivered at the surface of airway mucosa lining either nasal or lung tissue (16, 27, 31, 43). The  
366 functional activation of DC is not due to direct TLR5 signaling in DC (such as transepithelial DC)  
367 but rather to activation relayed by TLR5-stimulated epithelium. Our study demonstrated that the  
368 adjuvant effect is primarily driven by cDC2s. It remains to be determined how GM-CSF  
369 specifically impacts cDC2. The cDC2 phenotype can vary from the CD11b<sup>+</sup> profile found in the  
370 lungs to the CD103<sup>+</sup>CD11b<sup>+</sup> profile found in the gut's mucosal compartment. By using FLT3L-  
371 derived BMDCs that are known to give rise to cDC2s and cDC1s (i.e. cells that closely resemble  
372 the cDCs found in the lung), we were able to identify the role of the cDC2s. Since flagellin can  
373 directly activate cDC2s (21-23) (due to their TLR5 expression), we used cDCs from *Tlr5*<sup>-/-</sup> animals  
374 in order to analyze solely the flagellin-independent activation effect. It appears that native flagellin  
375 (and probably the recombinant flagellin FliC<sub>Δ174-400</sub> used in the present study) is rapidly degraded  
376 in the airways and translocates poorly in the lung parenchyma (26). Hence, the activation of cDC2s  
377 by flagellin in the lung mucosal compartment is dependent on factors that are released by AECs.  
378 We demonstrated here that GM-CSF released by FliC<sub>Δ174-400</sub>-stimulated AECs can activate cDC2s  
379 both *in vitro* and *in vivo*. Our *in vitro* data on FLT3L-derived cDCs stimulated with conditioned  
380 medium from FliC<sub>Δ174-400</sub>- activated AECs in the presence of GM-CSF-neutralizing antibodies  
381 suggest that GM-CSF is a critical or at least important cytokine in the process of cDC2 maturation  
382 (**Figure 3**). Next, GM-CSF neutralization studies in flagellin-treated mice concurred with the *in*  
383 *vitro* observations and evidenced a significantly lower number of activated cDC2s in the lung-  
384 draining lymph nodes (**Figure 4**). This finding is in line with literature reports on the importance

385 of GM-CSF as a key mediator of DC-driven responses to aero-allergens (41, 44, 45) but contrasts  
386 with previous reports in which flagellin-activated AECs promoted adaptive immunity through  
387 TSLP, IL-25 or IL-33 (27, 28). This difference may be due to the various flagellins that were used,  
388 especially the native form that harbors the hypervariable domain, and display a stronger TLR5-  
389 stimulating activity than the recombinant flagellin FliC $_{\Delta 174-400}$  (32). Consistently, a recent study  
390 highlighted that the hypervariable domain of flagellin contributes to the magnitude of TLR5  
391 signaling (46).

392 The current paradigm suggests that cDC2s in lung-draining lymph nodes are ideally placed to  
393 prime CD4<sup>+</sup> T cells, whereas cDC1s mainly cross-present antigens to CD8<sup>+</sup> T cells (47). We found  
394 a strong correlation between the number of cDC2s activated by AEC-derived GM-CSF on one  
395 hand and frequency of antigen-specific CD4<sup>+</sup> T cells on the other. Co-culture experiments with  
396 CD4<sup>+</sup> T cells and FLT3L-derived cDCs that had been exposed to the supernatant from flagellin-  
397 stimulated AEC conditioned medium clearly showed the role of GM-CSF-licensed cDCs in  
398 driving CD4<sup>+</sup> T cell proliferation (**Figure 5**). Moreover, the diminished antigen-specific CD4<sup>+</sup> T  
399 cell response in flagellin-adjuvanted animals treated with GM-CSF antibodies clearly  
400 demonstrated the importance of cDCs in CD4<sup>+</sup> T cell priming (**Figure 6**). These data correlate  
401 with observations on flagellin impact on B cell response and IgA production at the nasal mucosa  
402 (43).

403 The primary efficacy readout for many vaccines is the elicitation of antigen-specific antibodies,  
404 which is usually dependent on CD4<sup>+</sup> T cells. Our data suggest that intranasal administration of  
405 FliC $_{\Delta 174-400}$  efficiently primes antigen-specific CD4<sup>+</sup> T cells and elicits a strong mucosal and  
406 systemic antibody response (**Figure 1**). In response to flagellin-adjuvanted intranasal  
407 administration of OVA, a weak antigen-specific antibody response was observed in CD4-depleted

408 animals and in animals treated with GM-CSF-neutralizing antibodies (**Figure 6**). One possible  
409 explanation for this would be a cascade effect of GM-CSF neutralization on cDC2s, which in turn  
410 downregulates antigen-specific CD4<sup>+</sup> T cells and affecting overall antibody titers. It was recently  
411 reported that cDC2s are efficient vectors in the T follicular helper-dependent antibody response,  
412 due to their propensity to locate to the T-B cell border (48). Further work is needed to determine  
413 whether GM-CSF has a role in the precise anatomic localization of cDC2s within lymph nodes.  
414 Overall, our data suggest that GM-CSF has a critical role in triggering lung cDC2s to drive  
415 flagellin's activity as a mucosal adjuvant. Determining how AECs and the GM-CSF they produce  
416 affect cDC lung function and activation will constitute an important step in the development of  
417 new respiratory adjuvants for vaccines against major pathogens.

418

419 **ACKNOWLEDGMENTS**

420 We thank Laurence Mulard and Sylvie Bay at Institut Pasteur, Paris for the mass spectrometry  
421 analysis.

422

423 **AUTHOR CONTRIBUTIONS**

424 AV performed all animal, RT-qPCR, ELISA, and flow cytometry experiments. DC prepared the  
425 DC cultures and performed the experiments on the human airway epithelial cells. DF and LVM  
426 performed the experiments with the native flagellin FliC. AV and JCS designed experiments and  
427 wrote the manuscript. JCS supervised the experimental work as a whole.

428

429 **CONFLICT OF INTEREST**

430 The authors declare that the research was conducted in the absence of any commercial or financial  
431 relationships that could be construed as a potential conflict of interest.

432

433 **DATA AND MATERIALS AVAILABILITY**

434 The raw data supporting the conclusions of this manuscript will be made available by the authors,  
435 without undue reservation, to any qualified researcher.

616 **FIGURE LEGENDS**

617

618 **Figure 1. Flagellin's adjuvant activity requires TLR5 signaling and CD4 T lymphocytes.**

619 **(A-B)** C57BL/6JRj mice (n=5) were immunized by intranasal instillation with OVA protein  
620 (10 µg) alone or admixed with either FliC $\Delta$ 174-400 or FliC $_{TLR5mut}$  flagellin (2 µg) in PBS as a prime-  
621 boost regimen administered on days 0 and 21. Serum and MdLNs were sampled on day 28 and  
622 assayed respectively for OVA-specific antibodies (A) and the T cell response (B-C). **(A)** The  
623 OVA-specific antibody response in the serum of immunized animals. Titers of OVA-specific IgG  
624 were determined using an ELISA. **(B)** Antigen-specific lymphocyte proliferation. Cells isolated  
625 from the MdLNs of immunized animals were stained with CTV and stimulated with OVA protein  
626 *ex vivo* for 4 days. Representative flow cytometry plots of OVA-stimulated proliferating CD4 and  
627 CD8 lymphocytes (gated on live CD45<sup>+</sup>CD3<sup>+</sup>) are shown as an index of the dilution of CTV  
628 fluorescence. Proliferation is quantified as a percentage of total CD4 or CD8 cells. **(C)**  
629 C57BL/6JRj mice (n=5) received an intraperitoneal injection of either 200 µg of CD4-depleting  
630 antibody or an isotype control 24 hours prior to immunization with an admixture of FliC $\Delta$ 174-400 and  
631 OVA in a prime-boost immunization regimen, as described in A-C. The titer of OVA-specific  
632 antibodies in the serum of vaccinated mice was measured on day 28, as described in B. A Kruskal-  
633 Wallis test with Dunn's post-test for multiple comparisons was used to assess statistical  
634 significance. The results were expressed as the mean  $\pm$  SD and were representative of two  
635 experiments.

636

637 **Figure 2. TLR5 engagement on AECs promotes GM-CSF production.**

638 Airway epithelial cells from mice were grown at air liquid interface and stimulated by FliC $\Delta$ 174-  
639 400 (10  $\mu$ l of 1  $\mu$ g/ml of FliC $\Delta$ 174-400 were added to the air-exposed apical side). At the indicated  
640 times, AECs were sampled to prepare mRNA and cDNA for RT-qPCR and basolateral  
641 supernatants were sampled for cytokine analysis using an ELISA. The dotted line indicates the  
642 detection limit of the assay. **(A-B)** The flagellin-mediated activation of AECs from C57BL/6JRj  
643 (WT, n=9-10) was analyzed. **(A)** The time course of flagellin-mediated gene transcription. The  
644 AECs were lysed to extract RNA and gene expression was quantified as described in the Materials  
645 and Methods section. **(B)** Secretion of GM-CSF at 24h post-treatment, measured using an ELISA  
646 according to the manufacturer's instruction. Intergroup comparisons were performed using a  
647 Mann-Whitney unpaired t test. **(C)** The TLR5-dependent stimulation. Levels of GM-CSF in the  
648 supernatant of FliC $\Delta$ 174-400-stimulated AECs derived from *Tlr5*<sup>-/-</sup> or WT mice (n=6) were measured  
649 at the indicated times using an ELISA. **(D)** C57BL/6JRj mice (n=8 per group) were treated (or not)  
650 intranasally with FliC $\Delta$ 174-400 (2  $\mu$ g) in PBS. Bronchoalveolar lavages were sampled at 4 h and 8 h,  
651 and GM-CSF levels were measured using an ELISA. Time points were compared using a Kruskal-  
652 Wallis one-way ANOVA with Dunn's post-test. The results were representative of three  
653 experiments.

654

655 **Figure 3. The *in vitro* activation of FLT3L-derived BMDCs by flagellin-stimulated AECs**  
656 **depends on GM-CSF.**

657 **(A)** Schematic representation of the experimental design. FLT3L-derived BMDCs from *Tlr5*<sup>-/-</sup>  
658 mice were stimulated for 18 h with conditioned medium from FliC $\Delta$ 174-400-treated AECs in the  
659 presence of GM-CSF-neutralizing antibodies or an isotype antibody control. **(B)** Representative  
660 flow cytometry plots of stimulated, FLT3L-derived BMDCs gated on the cDC2 (live

661 CD45<sup>+</sup>CD11c<sup>+</sup>MHCII<sup>+</sup>CD11b<sup>+</sup>CD24<sup>dim</sup>) population expressing the activation markers CD80 and  
662 CD86. Untreated BMDCs were used to estimate the background fluorescence intensity. **(C)**. Total  
663 numbers of activated cDC2 cells and the median fluorescence intensity for CD80 and CD86 on  
664 cDC2s after treatment. Groups were compared using a two-way ANOVA with Tukey's post-test.  
665 The results were representative of four experiments.

666

667 **Figure 4. GM-CSF from AECs licenses DCs to stimulate antigen-specific CD4 lymphocytes.**

668 **(A)** Schematic representation of the experimental design. FLT3L-derived BMDCs from *Thr5*<sup>-/-</sup>  
669 mice were stimulated for 18 h with conditioned medium from FliC<sub>Δ174-400</sub>-treated AECs in the  
670 presence of GM-CSF-neutralizing antibodies or an isotype antibody control. The BMDCs were  
671 next washed and incubated for 4 h with OVA<sub>323-339</sub> MHCII-specific peptide before co-culture for  
672 4 days with CTV-stained, naïve, OVA-specific CD4 lymphocytes from OTII mice. **(B-C)**  
673 Proliferation of CD4 T cells (gated as live CD45<sup>+</sup>CD3<sup>+</sup>CD4<sup>+</sup>Vα2<sup>+</sup>). The percentage of dividing  
674 CD4 T cells (as measured by the dilution of CTV fluorescence) was measured using flow  
675 cytometry. Mock BMDCs (not conditioned) co-cultured with CTV-stained CD4 T cells were used  
676 to estimate background levels **(B)**. Representative histograms of CTV dilution. **(C)** Quantification  
677 of CD4<sup>+</sup> T cell proliferation, using independent conditioned medium (n=5). Groups were  
678 compared in a two-way ANOVA with Tukey's post-test. The results were representative of three  
679 experiments.

680

681 **Figure 5. GM-CSF regulates the flagellin-mediated activation of DCs in MdLNs.**

682 **(A)** Experimental design. C57BL/6JRj mice (n=5 to 6) were treated with a GM-CSF-neutralizing  
683 antibody or an isotype antibody control 2 hours prior to and then upon administration of flagellin

684 FliC $\Delta$ 174-400. All treatments were given intranasally in a total of volume of 30  $\mu$ l per treatment. The  
685 DC populations in the MdLN were analyzed at 18 hours, using flow cytometry. Dendritic cells  
686 were identified as CD11c<sup>+</sup>MHCII<sup>+</sup> cells within the live CD45<sup>+</sup>Lin<sup>neg</sup> population. **(B)**  
687 Representative dot plots of MdLN cDCs. **(C)** The numbers of cDC2s are quoted as the percentage  
688 of total CD45<sup>+</sup> cells. **(D)** Activation of MdLN cDC2s. The numbers of cDC2s expressing  
689 CD80 and CD86 are quoted as a percentage of total CD45<sup>+</sup> cells. **(E)** Median fluorescence intensity  
690 of CD80 in the activated cDC2 population. Groups were compared using a Kruskal-Wallis one-  
691 way ANOVA with Dunn's post-test. The results were representative of three experiments.

692

693 **Figure 6. Neutralization of GM-CSF reduces flagellin's adjuvant activity.**

694 **(A)** Experimental design. C57BL/6JRj mice (n=8) were immunized by intranasal instillation with  
695 OVA protein (10  $\mu$ g) alone or with OVA and flagellin FliC $\Delta$ 174-400 (2  $\mu$ g) in PBS as a prime-boost  
696 regimen administered on days 0 and 21. Two hours prior to and upon immunization, the animals  
697 were treated intranasally with GM-CSF-neutralizing antibodies or an isotype antibody control  
698 (60  $\mu$ g) in PBS. Serum, BAL, and MdLNs were sampled on day 28 to measure the OVA-specific  
699 T cell response (B) and OVA-specific antibody titer (C), respectively. **(B)** Antigen-specific  
700 lymphocyte proliferation. Cells isolated from the MdLNs of immunized animals were stained with  
701 CTV and stimulated with OVA protein *ex vivo* for 4 days. Representative flow cytometry plots of  
702 OVA-stimulated proliferating live CD45<sup>+</sup>CD3<sup>+</sup>CD4<sup>+</sup> are shown as a measure of the CTV  
703 fluorescence dilution. Proliferation was quantified as a percentage of total CD4<sup>+</sup> T cells. **(C)** The  
704 OVA-specific antibody response in serum and BAL of immunized animals. The dotted line  
705 indicates the OVA-specific IgG titers elicited in OVA/PBS immunized animals. Levels of OVA-

706 specific IgG were measured using an ELISA. Groups were compared using a Mann-Whitney  
707 unpaired t test.

Figure 6

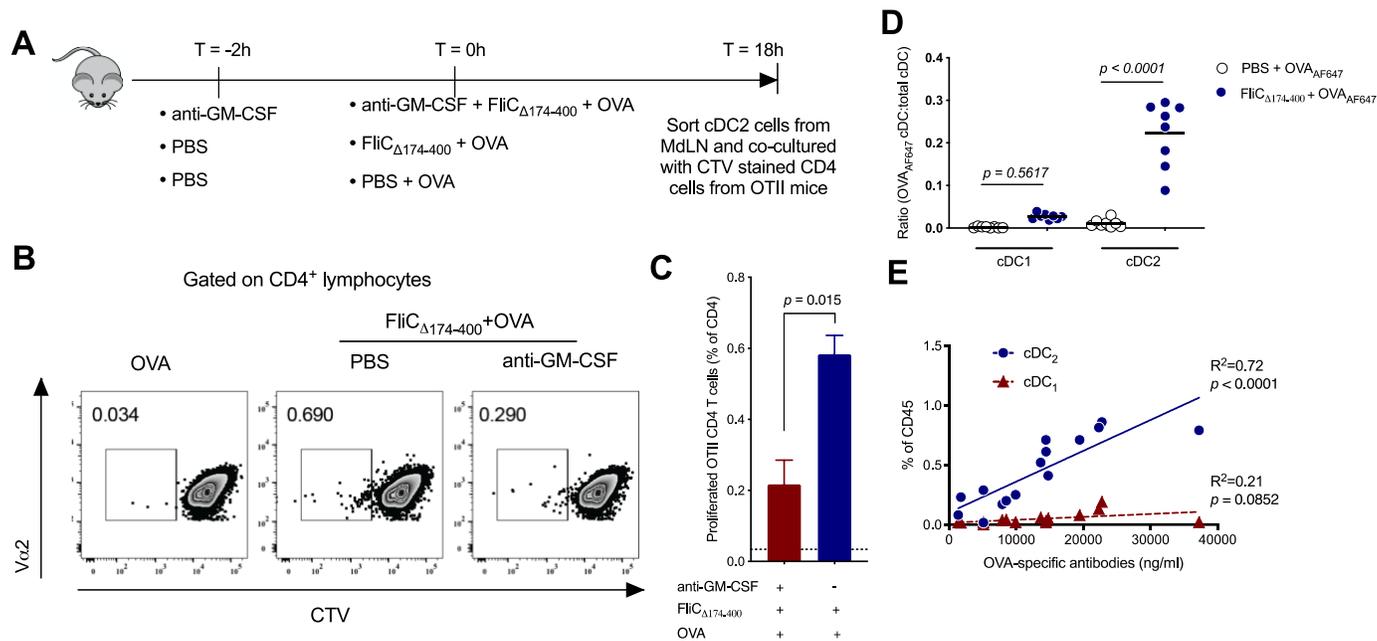

### Figure S1. Flagellin stimulates OVA-specific cytokine production by mediastinal lymph node cells.

The biophysical characteristics of recombinant flagellin FliC $\Delta$ 174-400 (expressed and purified from *E. coli*) was assessed as described in A-C. **(A)** Mass spectrometry analysis of the protein yielded a single peak of the expected molecular weight (29 kDa). The insert shows the SDS-PAGE analysis of the indicated amounts (in  $\mu$ g) of recombinant protein, followed by Coomassie staining. **(B)** *In vitro* activity of the recombinant protein, as measured in a Caco-2 cell-based assay. The reporter cell line contains a luciferase transgene that is driven by the *CCL20* promoter. Flagellin FliC $\Delta$ 174-400 that lacked TLR5 activity (FliC $\Delta$ TLR5mut) and trypsin-treated FliC $\Delta$ 174-400 were used as controls. **(C)** *In vivo* functional analysis of FliC $\Delta$ 174-400. *Tlr5*<sup>-/-</sup>, *Tlr4*<sup>-/-</sup> or C57Bl/6JRj (WT) mice were given an intranasal instillation of 2  $\mu$ g of FliC $\Delta$ 174-400, PBS, or trypsin-treated FliC $\Delta$ 174-400. BAL samples were taken at 6 hours, and the CCL20 level was determined using an ELISA. Cellular response to vaccination was analyzed as follows in **(D)**: C57BL/6JRj mice (n=5) were immunized by intranasal instillation with OVA protein (10  $\mu$ g) alone or OVA admixed with either FliC $\Delta$ 174-400 or FliC $\Delta$ TLR5mut flagellin (2  $\mu$ g) in PBS as a prime-boost regimen administered on days 0 and 21. Mediastinal lymph nodes were sampled on day 28 and pooled, and OVA-specific cytokine production was assessed. Levels of IFN $\gamma$  and IL-2 levels in the supernatant of OVA-stimulated MdLN cells were measured using an ELISA. The dotted line indicates the assay's limit of detection. The results were representative of two experiments (a pool of two MdLNs and a pool of three MdLNs per group).

### Figure S2. Airway epithelium and conducting airways respond to flagellin stimulation

(A-B) Freshly isolated lung alveolar epithelial cells are activated by flagellin. Lungs that were isolated from *Tlr5*<sup>-/-</sup> or C57BL/6JRj (WT) mice were digested with dispase to obtain a cell suspension. Following negative selection using magnetic beads and antibodies specific for CD45, CD31, and Ter119, the cells were analyzed for purity (A). The cells before and after selection were stained with an antibody specific for airway epithelial cells (Epcam<sup>+</sup>). To further differentiate between type I and type II alveolar epithelial cells, additional markers such as podoplanin (type I) and CD74 (type II) were included in the flow cytometry analysis (B). The alveolar epithelial cells were allowed to rest for 18 hours after isolation. Next, the cells were counted and seeded at  $2 \times 10^5$  in each well of a 96 well and stimulated with 1  $\mu$ g/ml of FliC $_{\Delta 174-400}$  in PBS for 6 hours. The RNA was isolated from stimulated cells and analyzed for the upregulation of the indicated genes. (C-D) Expression of potential DC-activating cytokines in mouse lung and broncho-alveolar lavages in response to intranasal administration of native flagellin. C57BL/6JRj mice (n=4 per group) were intranasally administered with native flagellin FliC (1  $\mu$ g in 20  $\mu$ l PBS). Total lung and broncho-alveolar lavages were sampled at 2, 4, 8, 18, 24, and 36 hours post-instillation. Lung protein extracts (C) and broncho-alveolar lavages (D) were prepared and cytokines were then measured by specific ELISA. The dotted line indicates the detection limit of the ELISA assay. Data represent the mean  $\pm$  SEM and are representative of 1-2 experiments (\*p<0.05).

### Figure S3. GM-CSF regulates the flagellin-mediated adjuvant effect by modulation of type 2 conventional dendritic cells

(A-C) GM-CSF regulates the flagellin-mediated DC-dependent priming of CD4 lymphocytes. (A) Experimental design. C57BL/6JRj mice (n=5) were treated with a GM-CSF-neutralizing antibody or PBS two hours prior to and then upon administration of flagellin FliC<sub>Δ174-400</sub>. All treatments were given intranasally in a total of volume of 30  $\mu$ l per treatment (OVA protein (10  $\mu$ g) alone or with OVA and flagellin FliC<sub>Δ174-400</sub> (2  $\mu$ g)). At 18 hours, MdlNs were sampled, and cDC2 were sorted as CD11c<sup>+</sup>MHCII<sup>+</sup>CD11b<sup>+</sup>CD103<sup>neg</sup> cells within the live CD45<sup>+</sup>Lin<sup>neg</sup>SiglecF<sup>neg</sup> population. Then cells were co-cultured for 4 days with CTV-stained, naïve, OVA-specific CD4 lymphocytes from OTII mice. (B) Proliferation of CD4 T cells. The percentage of dividing CD4 T cells (as measured by the dilution of CTV fluorescence into live CD45<sup>+</sup>CD3<sup>+</sup>CD4<sup>+</sup>V $\alpha$ 2<sup>+</sup> cells) was measured using flow cytometry. (C) Representative histograms of CTV dilution. Groups were compared using a Mann-Whitney unpaired t test. (D) The flagellin-activated cDC2s that capture antigen following intranasal instillation are found in the MdlNs. C57BL/6JRj mice (n=8) were intranasally administered with 10  $\mu$ g of OVA<sub>AF647</sub> or 2  $\mu$ g of FliC<sub>Δ174-400</sub> in PBS. The mice's MdlNs were sampled 18 hours after immunization and stained for cDC1s and cDC2s. Ratios of OVA<sub>AF647</sub>-associated cDC1s and cDC2s to total cDCs in the MdlNs. Groups were compared in a one-way ANOVA with Tukey's post-test. The results were representative of two independent experiments. (E). Neutralization of GM-CSF is correlated with the adjuvant effect of flagellin. The correlation between cDC1 or cDC2 counts and the titer of OVA-specific antibodies elicited by the immunization with FliC<sub>Δ174-400</sub> and OVA along with GM-CSF-neutralizing antibodies. The results from OVA-specific antibodies that were elicited in animals after a prime-boost with FliC<sub>Δ174-400</sub> and GM-CSF antibody were plotted against the total frequencies of cDC2s and cDC1s (gated on CD45 live cells) in the MdlNs (18 hours) after exposure to FliC<sub>Δ174-400</sub> and GM-CSF antibody. Correlations were assessed by calculating Pearson's coefficient.
