2 ABSTRACT  
3

4 The native microenvironment of mesenchymal stem cells (hMSCs) - the  
5 extracellular matrix (ECM), is a complex and heterogenous environment  
6 structured at different scales. The present study aims at mimicking  
7 the hierarchical microorganization of proteins or growth factors within  
8 the ECM using the photolithography technique. Polyethylene  
9 terephthalate (PET) substrates were used as a model material to  
10 geometrically defined regions of RGD + BMP-2 or RDG + OGP mimetic  
11 peptides. These ECM-derived ligands are under research for regulation  
12 of mesenchymal stem cells osteogenic differentiation in a synergic  
13 manner. The hMSCs osteogenic differentiation was significantly  
14 affected by the spatial distribution of dually grafted peptides on  
15 surfaces, and hMSCs cells reacted differently according to the shape  
16 and size of peptide micropatterns. Our study demonstrates the presence  
17 of a strong interplay between peptide geometric cues and stem cell  
18 differentiation toward the osteoblastic lineage. These tethered  
19 surfaces provide valuable tools to investigate stem cell fate  
20 mechanisms regulated by multiple ECM cues, thereby contributing to the  
21 design of new biomaterials and improving hMSCs differentiation cues.

## 50 1. Introduction

51 In the field of bone tissue engineering, mesenchymal stem cells (MSCs)  
52 are considered as good potential candidates due to their high  
53 proliferation rate, multipotency and bioavailability.(1) One of the  
54  
55  
56  
57

1  
2 hypotheses is that, MSCs travel from their niche to the needed  
3  
4 site to repair the injured tissues and restore their functions.(2) The  
5  
6 stem cell niche is a highly structured and complex microenvironment  
7  
8 where the stem cell renewal and differentiation take place.(3) The key  
9  
10 component of these microenvironments is the extracellular matrix (ECM).  
11  
12 The ECM influences the MSCs fate through various stimuli, which can be  
13  
14 biological, chemical or even mechanical. Though, the cell response  
15  
16 depends on the abundance and distribution of the biochemical molecules  
17  
18 in the ECM of the stem cell niche.(4) For example, during the MSCs  
19  
20 proliferation phase, the native ECM has a higher concentration in  
21  
22 fibroblast growth factor-2 (5) while, during the osteogenic  
23  
24 differentiation, the ECM is richer in bone morphogenic protein-2 (BMP-  
25  
26 2) and organization of the ECM undergoes a remodeling.(6)

27  
28  
29 Based on this knowledge, many strategies to translate the native ECM  
30  
31 features to *in vitro* models used these growth factors to control the  
32  
33 MSCs fate.(7,8) A traditional approach consists in the immobilization  
34  
35 of these biochemical cues onto the surface of bioinert materials in  
36  
37 order to mimic physiological conditions.(9) Moreover, coatings of  
38  
39 adhesion proteins and growth factors onto materials have been used  
40  
41 since a combination effect, regulating osteogenesis among others. It  
42  
43 is now demonstrated that integrins plays a key role in osteogenesis  
44  
45 while located nearby growth factors receptors.(10-13) Albeit,  
46  
47 researchers are trying to create the ideal biomaterial through surface  
48  
49 modification in order to satisfy the properties of the native ECM.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2 A promising way for the development of ideal biomaterials involves a  
3  
4 certain level of attention to the spatial arrangement of the native  
5  
6 ECM, which has been identified as a trigger during the stem cell  
7  
8 differentiation.(7,14-19) As a matter of fact, during proliferation  
9  
10 and differentiation, stem cells encounter a temporally and spatially  
11  
12 controlled mix of biochemical cues.(20,21) This knowledge is supported  
13  
14 by various *in vitro* studies which highlight the fact that very distinct  
15  
16 cellular responses can be obtained through the spatial organization of  
17  
18 ECM biomolecules.(16) Thus, biomolecules patterning of adhesion  
19  
20 molecules and growth factors could be the next step toward the  
21  
22 elaboration of biomaterials to mimic the native ECM *in vitro*.  
23  
24

25  
26  
27 By transferring the recent developments in microengineering technology  
28  
29 to surface modification, the patterning of biomolecules onto the  
30  
31 surface of a biomaterial can now be performed. The field of  
32  
33 biomaterials has been extensively using microfabrication techniques to  
34  
35 replicate the complexity of the native ECM.(22) The study presented  
36  
37 herein describes a technique to spatially pattern two mimetic peptides  
38  
39 onto a model material, polyethylene terephthalate (PET) films. The  
40  
41 peptides used in this study are RGD, a cell adhesion promoter, and  
42  
43 BMP-2 or OGP<sub>10-14</sub> (osteogenic growth peptide), to induce stem cell  
44  
45 osteogenic differentiation.(13,23,24) The RGD sequence and BMP-2  
46  
47 mimetic peptides are known to act synergistically to promote osteogenic  
48  
49 differentiation when randomly co-tethered onto a biomaterial  
50  
51 surface.(18,23,25) Spatial organization of ECM biomolecules has  
52  
53 already been used to control MSCs fate, but with confined single cells  
54  
55  
56  
57  
58  
59  
60

1  
2 (26,27) or with different cell type.(28,29) Moreover, most of these  
3  
4 studies were focusing on the impact of organized tethered ligands on  
5  
6 cellular adhesion. Our approach combined a cell adhesion promoter -  
7  
8 the RGD peptide - and peptides known to induce osteogenic  
9  
10 differentiation - the BMP-2 mimetic peptide and OGP<sub>10-14</sub>. These peptides  
11  
12 were combined according to different shapes (squares, rectangles,  
13  
14 hexagons) or different square sizes at the micrometric scale to control  
15  
16 the cell adhesion while promoting the osteogenic differentiation, to  
17  
18 closely mimic the native ECM and gather information about the stem cell  
19  
20 interaction with their microenvironment.  
21  
22

## 23 24 25 2. Materials and Methods

### 26 27 2.1. Materials

28  
29 PET samples were taken from a commercial crystalline biaxially-oriented  
30  
31 film obtained from GOODFELLOW (LILLE, France). The bi-oriented film had a  
32  
33 thickness of 75  $\mu\text{m}$ . Inorganic reagents (NaOH,  $\text{KMnO}_4$ ,  $\text{H}_2\text{SO}_4$ , HCl, glacial  
34  
35 acetic acid), acetone, acetonitrile, dimethylaminopropyl-3-  
36  
37 ethylcarbodiimideethylcarbodiimide hydrochloride (EDC), N-  
38  
39 hydroxysuccinimide (NHS) and 2-(N-morpholino)-ethanesulfonic acid  
40  
41 (MES), and toluidine blue-O (TBO) were purchased from SIGMA-ALDRICH (LYON,  
42  
43 France). GRGDSPC (RGD), GYGFGG (OGP), RKIPKASSVPTELSAISMLYL, which is  
44  
45 a BMP-2 mimetic peptide previously identified by our group (BMP-2)  
46  
47 (18,19,30), GRGDSPC-TAMRA, and RKIPKASSVPTELSAISMLYL-FITC fluorescent  
48  
49 peptides were synthesized by GENECUST, (ELLANGE, Luxembourg).  
50  
51  
52  
53

### 54 55 2.2. Methods

56  
57  
58  
59  
60

### 2.2.1. Surface preparation of PET and covalent grafting of the different peptides

PET surfaces were modified according to Chollet *et al.* (31) with some modifications. Briefly, PET was hydrolyzed and oxidized in order to create carboxyl groups on the surface (labeled as ``PET-COOH``). Then, the surfaces were immersed in a solution of EDC (0.2 M) + NHS (0.1 M) + MES (0.1 M) in MilliQ water for activation.

### 2.2.2. Preparation of resist patterned surfaces

Resist patterns were created on glass substrates using photolithography. Briefly, photosensitive resist S1818 (CHIMIE TECH, France) was coated on glass surfaces and spun at 3000 rpm for 30 s, leading to a homogenous photoresist of approximately 1  $\mu\text{m}$ . The surfaces were then baked at 100  $^{\circ}\text{C}$  for 60 s prior exposure to a pattern of light emitted by UV lamp (365 nm, 19,5 mW/cm<sup>2</sup>, contact mode, 50 Hz, exposure time: 8 s) through photomasks with patterns of different geometries (see Figure 1) (Département de génie électrique et de génie informatique, Université de Sherbrooke, QC, Canada). Subsequently, the exposed resist was developed by immersing the substrates in Microposit Developer solution (MF319, CHIMIE TECH, France) for 40 s. Finally, the samples were washed with deionized water, to remove any traces of developed resist, and dried with nitrogen gas (Figure 1).

### 2.2.3. Peptide grafting and patterning

The covalent grafting of peptides was achieved as described in a previous publication.(32) Briefly, the activation step was followed by creating resist patterns on activated surfaces using photolithography

1  
2 as described in the previous paragraph. Finally, resist patterned  
3  
4 surfaces were immersed in peptide solution (peptides dissolved in PBS  
5  
6 at the concentration of  $10^{-5}$ M) for 16h at room temperature. After  
7  
8 reaction, samples were washed with deionized water under agitation,  
9  
10 and then immersed in acetone for 30 seconds to remove the resist  
11  
12 pattern, resulting in peptide patterns surrounded with activated  
13  
14 domains. Then the second peptide was grafted following the same  
15  
16 protocol. Finally, substrates were rinsed and sonicated with MilliQ  
17  
18 water (Figure 2). Patterns of RGD-TAMRA and BMP-2-FITC or OGP-FITC  
19  
20 peptides developed using this protocol were shaped as hexagons, squares  
21  
22 or rectangles (Figure 1). Unpatterned and unfunctionalized PET surfaces  
23  
24 functionalized were also prepared and used as controls for biological  
25  
26 experiments.  
27  
28  
29

#### 30 31 32 2.2.4. Surface characterization

33  
34 The covalent grafting of peptides, the density of grafted peptides as  
35  
36 well as the surface roughness after each step of surface modification  
37  
38 were evaluated in a previous work on unpatterned PET surfaces using X-  
39  
40 ray photoelectron spectroscopy, fluorescence microscopy, contact  
41  
42 angle, and atomic force microscopy (32). In the present work, we have  
43  
44 focused on evaluating the efficiency of peptide patterning using  
45  
46 fluorescence microscopy and optical interferometry. On resist  
47  
48 patterned surfaces, fluorescence microscopy (LEICA DM5500B, WETZLAR,  
49  
50 Germany) was used to characterize the shape of resist patterns while  
51  
52 optical interferometry (Bruker Nano-NT9080, KARLSRUHE, Germany) was  
53  
54 employed to measure the pattern dimensions. Resist patterns were  
55  
56  
57  
58  
59  
60

1  
2 visible under fluorescence because the S1818 resist is auto-fluorescent  
3  
4 when excited with a 543nm laser line. Optical interferometry  
5  
6 measurements were carried out on dry samples, at room temperature,  
7  
8 using the vertical scanning interferometry mode with a vertical  
9  
10 resolution of approximately 2 nm. The interferograms were digitalized  
11  
12 with a CCD camera and converted into 2D topographic maps. Pattern  
13  
14 dimensions, according to the X and Y axes, were measured on these maps  
15  
16 using Veeco software.

17  
18  
19  
20  
21 These PET surfaces containing resist patterns were then used as a  
22  
23 template for fluorescent RGD and BMP-2 or OGP patterning. Finally, the  
24  
25 spatial distribution of peptides was visualized under fluorescence  
26  
27 microscopy (Leica microsystem DM5500B, microscope with a motorized,  
28  
29 programmable stage using a CoolSnap HQ camera controlled by Metamorph  
30  
31 7.6).

#### 32 33 34 35 2.2.5. Cell culture

36  
37 Human mesenchymal stem cells (hMSCs) from bone marrow (one donor)  
38  
39 purchased from PromoCell (Heidelberg, Germany), were grown in  
40  
41 mesenchymal stem cell basal media (MSCBM2) (PromoCell) in a humidified  
42  
43 atmosphere containing 5% (vol/vol) CO<sub>2</sub> at 37 °C. For each experiment,  
44  
45 hMSCs between passages 4 and 5 were seeded on PET materials at at an  
46  
47 identical density of 5,000 cells/cm<sup>2</sup> for all materials in serum-free  
48  
49 α-MEM during the first 6 h. The medium was then changed to α-MEM  
50  
51 supplemented with 10% (v/v) fetal bovine serum FBS (Gibco) with no  
52  
53 additional growth factors and was changed every 72 h. hMSC  
54  
55  
56

1  
2 differentiation on the different PET substrates was evaluated after  
3  
4 2 weeks of cell culture. Due to the large number of materials (more  
5  
6 than 140 materials) required to perform the biological analyses, the  
7  
8 decision was made to perform cell cultures at one specific time point.  
9  
10

#### 11 2.2.6. RT Quantitative Real-Time PCR

12 hMSCs were lysed in TRIZOL reagent (Invitrogen) to isolate the total  
13  
14 RNA. TurboDNA free kit (Ambion) was used to remove contaminating DNA  
15  
16 from RNA preparations. 2 µg of purified total RNA were used to  
17  
18 synthesize cDNA using Thermo Scientific Maxima Reverse Transcriptase  
19  
20 (Thermo Scientific) and random primers (Thermo Scientific). cDNA  
21  
22 aliquots (4 ng) were then amplified in 10 µL reaction volume containing  
23  
24 500 nM primers and SsoAdvanced™ Universal SYBR® Green Supermix  
25  
26 (Biorad) using CFX96™ Real-Time PCR Detection System (Biorad). PCR  
27  
28 cycling parameters were as follow: denaturation at 95 °C for 30 s  
29  
30 followed by 40 cycles of PCR reactions (95 °C for 5 s and 60 °C for 10  
31  
32 sec). Cq values for the gene of interest were normalized against two  
33  
34 genes: RPC53 and PPIA. Bestkeeper software was used to determine  
35  
36 normalization effectiveness of each reference gene among all samples.  
37  
38 The relative expression levels were calculated using the comparative  
39  
40 method ( $2^{-\Delta\Delta C_t}$ ) and controls were arbitrarily set at 1. Primers used  
41  
42 for amplification are listed in Table 1.  
43  
44  
45  
46  
47

#### 48 2.2.7 Statistical Analyses

49 All data were expressed as the mean ± standard deviation (SD) and  
50  
51 analyzed by one-way analysis of variance (ANOVA) and Tukey's test for  
52  
53 multiple comparisons, using GraphPad Prism version 6.01 for Windows  
54  
55  
56  
57  
58  
59  
60

1  
2 (GraphPad Software, San Diego, CA, USA, [www.graphpad.com](http://www.graphpad.com)). Significant  
3  
4 differences were determined for p values of at least  $\leq 0.05$ . \*  $p \leq$   
5  
6 0.05, \*\*  $p \leq 0.01$ , and \*\*\*  $p \leq 0.001$ .

### 7 8 9 3. Results

#### 10 11 3.1. Characterization of patterned surfaces

12  
13 The grafting protocol to conjugate peptides on the patterned surfaces  
14  
15 was previously described.<sup>(18)</sup> Photolithography was used on activated  
16  
17 surface (PET-NHS) to create resist patterns. All the surfaces with the  
18  
19 resist patterns were assessed under fluorescence microscopy due to the  
20  
21 S1818 resist auto-fluorescence. Images clearly showed the precise  
22  
23 geometries shaped as hexagons, rectangles and squares (Figure 3). After  
24  
25 the qualitative assessment of the resist patterned surfaces, the  
26  
27 quantitative assessment of these surfaces was performed using optical  
28  
29 interferometry. The obtained surface profiles revealed that resist  
30  
31 pattern sizes are closed to the originally defined micro-sized features  
32  
33 (Table 2 and Figure 3).

34  
35  
36  
37  
38  
39 Then, the first fluorescent peptide to be grafted (RGD-TAMRA) was  
40  
41 putted into contact with the resist micropatterned surfaces. Therefore,  
42  
43 only the available area was grafted with the first peptide. After  
44  
45 removing the resist, the surfaces were placed into a solution of the  
46  
47 second peptide to graft (BMP-2-FITC or OGP-FITC). Fluorescence  
48  
49 microscopy confirmed the efficiency of peptide patterning. Images  
50  
51 showed identifiable patterns and exhibit the expected shapes  
52  
53 (hexagonal, squared and rectangular geometries) and size (Figure 4),  
54  
55  
56  
57  
58  
59  
60

1  
2 and the intensity profile exhibits no overlap of the different regions  
3  
4 (Figure 5). Surfaces for cell culture were produce in the exact same  
5  
6 way, from the same batch of materials.  
7

### 8 9 3.2. hMSCs osteogenic differentiation

10 First, it is worth mentioning that a previous work investigated the  
11 effect of the homogeneous conjugation of individual peptides (RGD, BMP-  
12 2, and OGP) (32). With few exceptions, these single-tethered peptide  
13 surfaces exhibited lower expressions for all three markers (RUNX2,  
14 collagen I  $\alpha$ -1, and OCN) investigated in the present study, therefore  
15  
16 pointing to a synergistic effect toward cell differentiation when the  
17 so-called adhesion and differentiation signal peptides were co-  
18  
19 conjugated on a surface. Accordingly, any additional marker expression  
20  
21 response measured while comparing homogeneous surface conjugation of  
22 the adhesion peptide (RGD) together with a differentiation peptide  
23 (BMP-2 or OGP) can only be attributed to pattern shapes or sizes.  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

#### 36 37 3.2.1. The extent of hMSCs osteogenic differentiation in response to 38 different shapes of patterns

39 The potential changes in hMSCs phenotype on the different shapes of  
40 patterned surfaces were assessed by RT-qPCR after 2 weeks of cell  
41 culture. Human MSCs seeded on oxidized PET in the same cell culture  
42 conditions were used as negative control. Surfaces conjugated with a  
43 mixture of RGD and BMP-2 peptides were first investigated. At first  
44  
45 sight, the results showed that the expression of RUNX2, an early  
46  
47 osteogenic marker, was significantly enhanced in the cells cultured on  
48  
49 the tethered surfaces, as compared to control surfaces (Figure 6A). On  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2 the other and, the organization of RGD and BMP-2 peptides as squares,  
3  
4 hexagons, or rectangles did not lead to additional RUNX2 expression  
5  
6  
7 as compared to the surface randomly conjugated with the mixture of  
8  
9 peptides. Similar trends were observed while considering ColI- $\alpha$ 1  
10  
11 expression, with significant differences recorded when RGD and BMP-2  
12  
13 are patterned as rectangles and hexagons as compared to the control  
14  
15 sample or to the surface homogeneously coated with both peptides  
16  
17 (Figure 6B). Finally, the OCN expression did not allowed to  
18  
19 discriminate among all investigated samples, likely because that the  
20  
21 culture time that was investigated in the present study was not long  
22  
23 enough to allow measuring differences in this marker expression (Figure  
24  
25 6 C).

26  
27  
28  
29 Surfaces with a mixture of RGD and OGP were also investigated.  
30  
31 In this case, the situation is less clear in terms of RUNX2  
32  
33 expression. Indeed, the presence of both RGD and OGP on the various  
34  
35 investigated samples clearly lead to an increase of the RUNX2  
36  
37 expression as compared to the control sample (Figure 6D). However, no  
38  
39 significant differences were evidenced among the various investigated  
40  
41 patterns. That said, the expression of ColI- $\alpha$ 1 shed more light on the  
42  
43 effect of the RGD and OGP organization on the surfaces as the squares  
44  
45 definitely lead to a significant increase of this marker with respect  
46  
47 to all other investigated samples (Figure 6E).  
48  
49 Again, it sounds that the culture time was not long enough  
50  
51 to enable measuring differences in the OCN expression, therefore  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2 providing an indication about the state of the differentiation level

3  
4 (Figure 6F).

5 Taken together, the data on both

23  
24 the RGD/BMP-2 and RGD/OGP surface patterning point toward an improved

25  
26 cell differentiation related to the peptide couple organization on the

27  
28 surface. In addition, it is also clear that an identical geometrical

29  
30 organization of the RDG/BMP-2 and RGD/OGP couples was not felt

31  
32 similarly by the hMSCs in terms of their differentiation.

33

40  
41  
42  
43  
44  
45 3.2.2. The extent of hMSCs osteogenic differentiation in response to  
46 different size of patterns

47 The potential changes in hMSCs phenotype on the surfaces patterned with  
48 different sizes of squares were assessed by RT-qPCR after 2 weeks of  
49 cell culture (Figure 7). Human MSCs seeded on oxidized PET in the same  
50 cell culture conditions were used as negative control. Surfaces with  
51 a mixture of RGD and BMP-2 peptides were first investigated. With the  
52  
53  
54  
55  
56  
57

1  
2 exception of the 100x100 sample, the expression of RUNX2 (Figure  
3  
4 7A) is more important on the RGD/BMP-2 tethered surfaces (random, 50x50  
5  
6 and 25x25) as compared with the control sample, with the most important  
7  
8 expression being observed on the smallest size of square pattern. Of  
9  
10 note, a nice gradation of the RUNX2 expression was observed from  
11  
12 the larger (100x100) to the smaller (25x25) RGD/BMP-2 tethered  
13  
14 surfaces. For the RGD/BMP-2 couple, the importance of the pattern size  
15  
16 on the cell differentiation behavior was also observed while measuring  
17  
18 the collagen I  $\alpha$ -1 and OCN expression (Figure 7B and 7C), as both  
19  
20 markers exhibited the highest measured level among all investigated  
21  
22 samples when cells were cultured on the 25x25 pattern.  
23  
24

25  
26  
27 The situation was somewhat different while investigating the effect of  
28  
29 peptide pattern size with the RGD/OGP couple. On one hand, the random,  
30  
31 100x100, and 50x50 samples all led to an almost equivalent four-fold  
32  
33 increase of the RUNX2 expression (Figure 7D) as compared to the  
34  
35 control sample. On the other hand, the expression of RUNX2 was  
36  
37 again higher on the smaller size pattern, that is the 25x25 sample. In  
38  
39 this case, this marker level of expression was eight times that of the  
40  
41 control sample and twice that of any other investigated RGD/OGP  
42  
43 conjugated surfaces, either homogeneously conjugated or patterned. For  
44  
45 this peptide couple, the expression of ColI- $\alpha$ 1 (Figure 7E) was  
46  
47 significantly higher only in the case of the medium size (50x50) and  
48  
49 OCN (Figure 7F) was not significantly impacted by the tethered peptides  
50  
51 in any cases.

#### 34. Discussion

Promoting a specific fate of hMSCs is a complex process involving different parameters such as cell morphology, gene expression and ECM protein concentration changes. *In vivo*, the osteogenic differentiation process is ruled through different stimuli, which can be chemical and/or physical in nature.(3,4) The differentiation of hMSCs in the stem cell niche is guided by those stimuli. *In vitro*, scientists are trying to reproduce the stem cell niche to promote stemness or induce a guided differentiation. The use of peptide appears to be a good solution to mimic the stem cell niche. For example, BMP-2 mimetic peptides were used *in vitro*, (18,23,33) in animal models (34) and are FDA approved for various surgeries such as spinal cord fusion procedure.(35,36) However, to overcome the diffusion of the mimetic peptide away from the implant when placed in the body, immobilization on biologically compatible biomaterials surface can be used.(37)

Osteogenesis is induced through the interaction of BMP-2 growth factor with its receptor - BMP transmembrane receptors type I and type II (BMPRI and BMPRII). BMP-2 preferentially interact with BMPRII which activate the phosphorylation of SMAD1/5/8 and their translocation into the nucleus. Following the translocation, RUNX2 expression is significantly improved as another early markers regulating osteoblast differentiation.(38) The expression of RUNX2 further activates the upregulation of osteoblast phenotype proteins.(39) Although BMP-2 peptide is greatly used in biomaterial strategies to promote bone regeneration, current strategies for the design of biomaterials for

1  
2 bone tissue engineering are using multiple peptides combined on the  
3  
4 surface of a biomaterial. (18,19,23) This strategy is used to mimic the  
5  
6 physiological situation, where a combinatorial effect of a mixture of  
7  
8 ligands synergize together to induce the differentiation process.  
9  
10 Ligand crosstalk has been investigated in order to differentiate stem  
11  
12 cells. For example, various combinations of BMP-2 (sequence used  
13  
14 KIPKASSVPTELSAISTLYL), osteopontine (OPN) and RGD were used to induce  
15  
16 the differentiation of rate MSCs cells. (40) An increase of ALP activity  
17  
18 and calcium content after 2 and 4 weeks on the hydrogels containing  
19  
20 RGD alone, and even further with the hydrogels containing the mixture  
21  
22 of RGD and BMP-2 and/or OPN. We recently demonstrated that the  
23  
24 expression of alkaline phosphatase is more important on surfaces  
25  
26 tethered with FHRRIKA and BMP-2 peptides together, without requiring  
27  
28 differentiation media during the cell culture. (32)  
29  
30  
31  
32

33  
34 Another growth factor which can induce hMSCs differentiation is  
35  
36 osteogenic growth peptide (OGP). This peptide has demonstrated an  
37  
38 ability to upregulate the differentiation of hMSCs and to promote the  
39  
40 mineralization of the matrix. Different studies demonstrated that its  
41  
42 capabilities are dependent to its concentration however it is  
43  
44 independent to the fact that the peptide is present in a soluble form  
45  
46 of tethered on the surface of a material. (13,24,41) The OGP sequence  
47  
48 has also been used in combination with the RGD sequence in order to  
49  
50 differentiate pre-osteoblasts (MC3T3) into osteoblasts on polymer  
51  
52 substrates (polyethylene oxide). (13) It is believed that the RGD  
53  
54 sequence binds to the integrins while the OGP sequence (no receptor  
55  
56  
57  
58  
59  
60

1  
2 identify up to date) causes differentiation into bone cells.(42) The  
3  
4 combination of these two peptides might enables cells to adhere and  
5  
6 differentiate on the same surface. Furthermore, we recently  
7  
8 demonstrated that the expression of OPN and RUNX2 is increased in  
9  
10 cells cultivated on PET surfaces tethered with RGD and OGP after two  
11  
12 weeks, without the addition of differentiation media.(32)  
13  
14  
15

16 The level of organization of the ECM ranges from the nano- to the  
17  
18 micro-scale. The present work aimed to mimic the micro-organization.  
19  
20 Pattern shapes (squares, rectangles, hexagons) have been inspired from  
21  
22 previous studies that reported that elongated and angular shapes  
23  
24 preferentially promote the differentiation toward osteoblastic  
25  
26 cells.(14,43,44) We have investigated similar sizes of the different  
27  
28 shapes of patterns with a combination of RGD and a growth factor  
29  
30 mimicking peptide (either BMP-2 or OGP) compared to a random  
31  
32 distribution. However, it is now demonstrated that biochemical cues  
33  
34  
35 distribution is not homogeneous within the ECM (45) and cells might be  
36  
37 sensitive to different size of pattern on a surface. Therefore,  
38  
39 different sizes of the square patterns were also investigated.  
40  
41  
42

43  
44 As shown in the results sections, hMSCs sense and respond to the various  
45  
46 size of dual peptide micropatterns. Indeed, the smallest size of  
47  
48 squares (25x25  $\mu\text{m}^2$ ) significantly enhanced RUNX2 expression after  
49  
50 two weeks of cell culture, whereas the largest sizes of patterns have  
51  
52 a similar response compared to randomly grafted peptide samples. These  
53  
54 results deliver indications that the hMSCs differentiation process can  
55  
56  
57  
58  
59  
60

1  
2 be triggered through both biochemical and geometric cues. Therefore,  
3  
4 the micro organization of the peptides as specific patterns appears to  
5  
6 be critical during the hMSCs differentiation.  
7

8  
9 The use of micro-sized geometric patterns to control the stemness  
10 character or induce stem cell differentiation is a rather recent topic.  
11  
12 Accordingly, few studies demonstrated the link between microscale  
13  
14 distribution and MSCs differentiation into specialized phenotypes.  
15  
16  
17  
18 McBeath *et al.* have used fibronectin islands onto polydimethylsiloxane  
19  
20 of different sizes (1024, 2025, and 10 000  $\mu\text{m}^2$ ) to culture MSCs for 1  
21  
22 week in mixed osteogenic/adipogenic media.(43) The results of this  
23  
24 study show that MSCs cultured on the largest micro-islands mainly  
25  
26 differentiate into osteoblasts, whereas those on smaller micro-islands  
27  
28 exhibits adipocytes characteristics. In our study, the most advanced  
29  
30 differentiation process is on the smallest pattern (625  $\mu\text{m}^2$ ) as  
31  
32 compared to the largest pattern (10 000  $\mu\text{m}^2$ ) and the random grafting.  
33  
34  
35  
36 That said, McBeath *et al.* made their investigation on a single pattern  
37  
38 element studying a single cell while the present study rather focused  
39  
40 on arrays of biofunctionalized patterns. Therefore, the cell  
41  
42 environment and the material on which the cells are cultured are  
43  
44 different and can lead to different results. The material can have a  
45  
46 great impact depending on the material hydrophilicity, charge,  
47  
48 mechanical properties.  
49  
50  
51

52  
53 Another study investigated the fate of MSCs on RGD patterns of  
54  
55 different geometries (circles, squares, triangles and stars) of 900  
56  
57  
58  
59  
60

1  
2  $\mu\text{m}^2$  on a poly(ethylene glycol) hydrogel.(14) In this study, the optimal  
3  
4 osteogenesis was observed on the star shape after one week of culture.  
5  
6 Whereas scientists still does not fully understand why specific  
7  
8 geometrical cues are able to induce the differentiation toward the  
9  
10 osteoblastic lineage, some tried to defined a general signaling  
11  
12 pathway.(14,15,43) In the current study, the use of different shapes  
13  
14 of grafted peptides appears to impact on the differentiation of stem  
15  
16 cells compared to the randomly tethered surfaces. As the expression of  
17  
18 ColI- $\alpha$ 1 was significantly higher in the case of the cells cultured on  
19  
20 rectangle-patterned surfaces with both RGD and BMP-2, this means these  
21  
22 cells are committed to the osteoblastic lineage.(46) In addition, the  
23  
24 cells in contact with the RGD/OGP peptide couple exhibit a stronger  
25  
26 engagement while cultured on surfaces presenting hexagonal and  
27  
28 rectangular features. In a previous study of our group,(32) the  
29  
30 possible synergetic effect between RGD and OGP was investigated and it  
31  
32 was demonstrated that the OGP sequence is more efficient to promote an  
33  
34 osteoblastic differentiation in presence of the RGD sequence while  
35  
36 grafted randomly on the surface of PET. In the present study, we  
37  
38 demonstrate that this synergetic effect between RGD and OGP peptide is  
39  
40 further enhanced while the peptides are tethered following a specific  
41  
42 shape (hexagonal or rectangular).

43  
44  
45  
46  
47  
48  
49  
50  
51 Although our study provides clear evidence that hMSCs can sense  
52  
53 geometrical cues in their environment, it appears that the size of  
54  
55 these patterns is also an important factor to consider  
56  
57 the differentiation process. Bilem *et al.* showed that the geometrical  
58  
59  
60

1 peptide arrangement was important to guide hMSCs differentiation using  
2 smaller pattern than the ones used in the present study. (18) However,  
3  
4  
5  
6  
7 the size of the investigated patterns in Bilem et al. work was between  
8  
9 10 to 200 times smaller than the patterns investigated in the present  
10  
11 study. With the present data, cells cultured on the smallest patterns  
12  
13 - independently from the peptide couple investigated - exhibit strong  
14  
15 ~~RUNX~~RUNX-2 expression and a higher expression of ColI- $\alpha$ 1 and OCN in the  
16  
17 case of RGD/BMP-2 peptide couple. Therefore, the pattern size appears  
18  
19 as the most important factor to consider when designing peptide  
20  
21 patterns on a flat surface for hMSCs differentiation. However, since  
22  
23 the random grafting of peptide, which can be considered as the smallest  
24  
25 size of pattern we can create, did not induce further differentiation  
26  
27 of the cells into the osteoblastic lineage, it can be hypothesized that  
28  
29 cells are responsive to geometrical features until a minimum feature  
30  
31 size. In addition, among the three investigated markers, RUNX2 was  
32  
33 clearly the first to be expressed. As RUNX-2 is the first of the  
34  
35 three markers to be expressed during osteogenic differentiation, (46),  
36  
37 it is likely that the differentiation of the cells cultured on the  
38  
39 patterned surfaces with basal media is at an early stage, but  
40  
41 nevertheless engaged into the process. Of note, some of the data  
42  
43 presented herein sometimes showed differentiation through the ColI- $\alpha$ 1  
44  
45 gene expression, without clear signs of differentiation coming from  
46  
47 the RUNX2 marker. However, these results were repeatedly measured. As  
48  
49 of now, the reason for such a behavior remains unclear.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2 By combining the results of the present investigation and literature,  
3  
4 we can draft the composite picture of an ideal biomaterial to induce  
5  
6 a fast differentiation toward the osteoblast lineage. Indeed, according  
7  
8 to our data, hMSCs differentiation into osteoblasts is promoted by  
9  
10 using a combination of RGD and BMP-2 peptide arranged on a flat  
11  
12 surface, (18,23) tethered on the surface using sharp motifs, (47)  
13  
14 preferentially elongated such as rectangles, and using a pattern size  
15  
16 equal or smaller than  $625 \mu\text{m}^2$ .  
17  
18  
19  
20  
21

22 This ideal material would be the best one to differentiate hMSCs toward  
23  
24 the osteoblastic lineage as our results show a higher expression of  
25  
26 RUNX2 (4 times higher) and an expression of OCN that is twice  
27  
28 higher (compared to the control) within 2 weeks of cell culture without  
29  
30 using osteogenic media.  
31  
32

33  
34 Further investigations are required to fully understand these  
35  
36 observations. However, it is likely that the smallest patterns lead to  
37  
38 much more crosstalk between RGD and BMP-2 or OGP, therefore regulating  
39  
40 the signalization pathways. Indeed, it is well established that RGD  
41  
42 peptides affect the colocalization of integrin and ligand receptors  
43  
44 which in turn, leads to cell commitment and differentiation. (17)  
45  
46  
47

#### 48 ~~45~~. Conclusion

49  
50  
51 2D model materials were engineered to investigate the impact of the  
52  
53 geometry and size micro-scale distribution of RGD peptides combined  
54  
55 with an osteogenic inducer peptide (BMP-2 or OGP). We have recently  
56

1  
2 demonstrated that homogeneously co-conjugated RGD/BMP-2 or RGD/OGP  
3  
4 peptides onto PET surfaces significantly enhanced hMSCs osteogenesis  
5  
6 as compared to the solely homogeneous grafting of BMP-2 or OGP  
7  
8 peptides. In the present study, we demonstrated that these same  
9  
10 combinations of peptides can further induce stem cell differentiation  
11  
12 when appropriately organized on the surface. The patterning must be  
13  
14 relatively small (area less than  $625 \mu\text{m}^2$ ) and sharp in terms of their  
15  
16 shapes (such as rectangles). Among all the concentrations that  
17  
18 were assessed, a 50/50 combination of RGD and BMP-2 appears to be the  
19  
20 best mixture to promote osteogenic differentiation. Taken together,  
21  
22 these results suggest that the combination of chemical and geometric  
23  
24 cues is able to direct stem cell fate without the need of  
25  
26 differentiation media. This surface modification strategy provides a  
27  
28 versatile platform for surface structuration and its optimization for  
29  
30 various biomaterials applications.

## FIGURE CAPTIONS

**Figure 1.** Scheme of the different shapes and sizes of patterns

**Figure 2.** Scheme of preparation of the pattern surfaces

**Figure 3.** Profilometry images of resist micropatterned surfaces showing

three different pattern geometries (hexagons, rectangles, squares).

**Figure 4.** Fluorescence images of the different patterned surfaces with RGD-TAMRA (labelled in red) and OGP-FITC (labelled in green). Scale

bar: 100  $\mu\text{m}$ .

**Figure 5.** Fluorescent intensity profile of the squared geometry with RGD-TAMRA (labelled in red) and OGP-FITC (labelled in green). Scale

bar: 100  $\mu\text{m}$ .

**Figure 6.** Gene expression dynamics after 2 weeks of RUNX~~unx~~-2, (A: RGD+BMP; D: RGD+OGP), ColI- $\alpha$ 1 (B: RGD+BMP; E: RGD+OGP) and osteocalcin (OCN) (C: RGD+BMP; F: RGD+OGP) on different size of patterns (n=5).

**Figure 7.** Gene expression dynamics after 2 weeks of RUNX~~unx~~-2, (A: RGD+BMP; D: RGD+OGP), ColI- $\alpha$ 1 (B: RGD+BMP; E: RGD+OGP) and osteocalcin (OCN) (C: RGD+BMP; F: RGD+OGP) on different shapes of patterns (n=5).

## TABLES

**Table 1.** Nucleotide sequences of primers used for quantitative RT-qPCR detection

Gene	Primer Sequence
<b>RUNX2</b>	5'-AAGTGCGGTGCAAACCTTTCT-3' (Forward)
	5'-TCTCGGTGGCTGGTAGTGA-3' (Reverse)
<b>Alkaline Phosphatase</b>	5'-ATGCCCTGGAGCTTCAGAAG-3' (Forward)
	5'-TGGTGGAGCTGACCCTTGAG-3' (Reverse)
<b>Osteocalcin</b>	5'-GACTGTGACGAGTTGGCTGA-3' (Forward)
	5'-CTGGAGAGGAGCAGAACTGG-3' (Reverse)
<b>Collagen I <math>\alpha</math>1</b>	5'-ACATGTTTCAGCTTTGTGGACC-3' (Forward)
	5'-TGATTGGTGGGATGTCTTCGT-3' (reverse)
<b>PPIA</b>	5'-CGGGTCCTGGCATCTTGT-3' (Reverse)
	5'-CAGTCTTGGCAGTGCAGATGA-3' (Reverse)
<b>RPC53</b>	5'-ACCCTGGCTGACCTGACAGA-3' (Forward)
	5'-AGGAGTTGCACCCTTCCAGA-3' (Reverse)

**Table 2.** Expected and measured size of the pattern features for the five different geometries.

	Expected size ( $\mu\text{m}$ )			Measured size ( $\mu\text{m}$ )		
	Length	Width	Gap	Length	Width	Gap
Hexagons	88	76.2	19	$81 \pm 1$	$73.6 \pm 0.5$	$18.7 \pm 0.5$
Squares 100x100	100		17	$100,2 \pm 0,8$		$17.0 \pm 0.7$
Squares 50x50	50		15.5	$49 \pm 1$		$16.3 \pm 0.7$

Squares 25x25	25		9	25.2 ± 0.1		8.8 ± 0.1
Rectangles	50	25	12.5	49.8 ± 0.6	24.8 ± 0.5	12.7 ± 0.5
